#### Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is intended through suggestion only and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. No representation or warranty is given and no liability is assumed by Microchip Technology Incorporated with respect to the accuracy or use of such information, or infringement of patents or other intellectual property rights arising from such use or otherwise. Use of Microchip's products as critical components in life support systems is not authorized except with express written approval by Microchip. No licenses are conveyed, implicitly or otherwise, under any intellectual property rights.

#### Trademarks

The Microchip name and logo, the Microchip logo, Accuron, dsPIC, KEELOQ, microID, MPLAB, PIC, PICmicro, PICSTART, PRO MATE, PowerSmart, rfPIC, and SmartShunt are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

AmpLab, FilterLab, MXDEV, MXLAB, PICMASTER, SEEVAL, SmartSensor and The Embedded Control Solutions Company are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Analog-for-the-Digital Age, Application Maestro, dsPICDEM, dsPICDEM.net, dsPICworks, ECAN, ECONOMONITOR, FanSense, FlexROM, fuzzyLAB, In-Circuit Serial Programming, ICSP, ICEPIC, Migratable Memory, MPASM, MPLIB, MPLINK, MPSIM, PICkit, PICDEM, PICDEM.net, PICLAB, PICtail, PowerCal, PowerInfo, PowerMate, PowerTool, rfLAB, rfPICDEM, Select Mode, Smart Serial, SmartTel and Total Endurance are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

SQTP is a service mark of Microchip Technology Incorporated in the U.S.A.

All other trademarks mentioned herein are property of their respective companies.

OHALITV MANAGEMENT OVOTEM

Microchip received ISO/TS-16949:2002 quality system certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona and Mountain View, California in October 2003. The Company's quality system processes and procedures are for its PICmicro® 8-bit MCUs, KEEL00® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.

# PIC18F1220/1320

### 18/20/28-Pin High-Performance, Enhanced Flash MCUs with 10-bit A/D and nanoWatt Technology

#### Low-Power Features:

- Power Managed modes:
  - Run: CPU on, peripherals on
  - Idle: CPU off, peripherals on
  - Sleep: CPU off, peripherals off
- Power Consumption modes:
  - PRI\_RUN: 150 μA, 1 MHz, 2V
  - PRI\_IDLE: 37 μA, 1 MHz, 2V
  - SEC\_RUN: 14  $\mu$ A, 32 kHz, 2V
  - SEC\_IDLE: 5.8 μA, 32 kHz, 2V
  - RC\_RUN: 110 μA, 1 MHz, 2V
  - RC\_IDLE: 52 μA, 1 MHz, 2V
  - Sleep: 0.1  $\mu\text{A},$  1 MHz, 2V
- Timer1 Oscillator: 1.1 μA, 32 kHz, 2V
- Watchdog Timer: 2.1 μA
- Two-Speed Oscillator Start-up

#### **Oscillators:**

- · Four Crystal modes:
  - LP, XT, HS: up to 25 MHz
  - HSPLL: 4-10 MHz (16-40 MHz internal)
- Two External RC modes, up to 4 MHz
- Two External Clock modes, up to 40 MHz
- Internal oscillator block:
  - 8 user-selectable frequencies: 31 kHz, 125 kHz, 250 kHz, 500 kHz, 1 MHz, 2 MHz, 4 MHz, 8 MHz
  - 125 kHz to 8 MHz calibrated to 1%
  - Two modes select one or two I/O pins
  - OSCTUNE Allows user to shift frequency
- Secondary oscillator using Timer1 @ 32 kHz
- Fail-Safe Clock Monitor
  - Allows for safe shutdown if peripheral clock stops

#### **Peripheral Highlights:**

- High current sink/source 25 mA/25 mA
- Three external interrupts
- Enhanced Capture/Compare/PWM (ECCP) module:
  - One, two or four PWM outputs
  - Selectable polarity
  - Programmable dead time
  - Auto-Shutdown and Auto-Restart
  - Capture is 16-bit, max resolution 6.25 ns (Tcy/16)
  - Compare is 16-bit, max resolution 100 ns (TCY)
- Compatible 10-bit, up to 13-channel Analog-to-Digital Converter module (A/D) with programmable acquisition time
- Enhanced USART module:
  - Supports RS-485, RS-232 and LIN 1.2
  - Auto-Wake-up on Start bit
  - Auto-Baud Detect

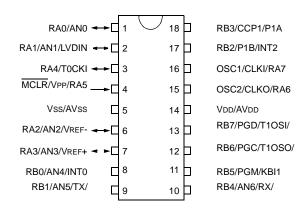

#### **Special Microcontroller Features:**

- 100,000 erase/write cycle Enhanced Flash program memory typical
- 1,000,000 erase/write cycle Data EEPROM memory typical
- Flash/Data EEPROM Retention: > 40 years
- Self-programmable under software control
- Priority levels for interrupts
- 8 x 8 Single-Cycle Hardware Multiplier
- Extended Watchdog Timer (WDT):
  - Programmable period from 41 ms to 131s
  - 2% stability over VDD and Temperature
- Single-supply 5V In-Circuit Serial Programming<sup>™</sup> (ICSP<sup>™</sup>) via two pins
- In-Circuit Debug (ICD) via two pins
- Wide operating voltage range: 2.0V to 5.5V

Device	Program Memory		Data Memory			40 1.4	ECCP		Timers

### TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at **docerrors@mail.microchip.com** or fax the **Reader Response Form** in the back of this data sheet to (480) 792-4150. We welcome your feedback.

#### Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000A is version A of document DS30000).

#### Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

- Microchip's Worldwide Web site; http://www.microchip.com
- Your local Microchip sales office (see last page)
- The Microchip Corporate Literature Center; U.S. FAX: (480) 792-7277

When contacting a sales office or the literature center, please specify which device, revision of silicon and data sheet (include literature number) you are using.

#### **Customer Notification System**

Register on our web site at www.microchip.com/cn to receive the most current information on all of our products.

### 1.0 DEVICE OVERVIEW

This document contains device specific information for the following devices:

• PIC18F1220 • PIC18F1320

This family offers the advantages of all PIC18 microcontrollers – namely, high computational performance at an economical price – with the addition of high endurance Enhanced Flash program memory. On top of these features, the PIC18F1220/1320 family introduces design enhancements that make these microcontrollers a logical choice for many high-performance, power sensitive applications.

#### 1.1 New Core Features

#### 1.1.1 nanoWatt TECHNOLOGY

All of the devices in the PIC18F1220/1320 family incorporate a range of features that can significantly reduce power consumption during operation. Key items include:

- Alternate Run Modes: By clocking the controller from the Timer1 source or the internal oscillator block, power consumption during code execution can be reduced by as much as 90%.
- **Multiple Idle Modes:** The controller can also run with its CPU core disabled, but the peripherals are still active. In these states, power consumption can be reduced even further, to as little as 4% of normal operation requirements.
- **On-the-fly Mode Switching:** The power managed modes are invoked by user code during operation, allowing the user to incorporate power-saving ideas into their application's software design.
- Lower Consumption in Key Modules: The power requirements for both Timer1 and the Watchdog Timer have been reduced by up to 80%, with typical values of 1.1 and 2.1  $\mu$ A, respectively.

#### 1.1.2 MULTIPLE OSCILLATOR OPTIONS AND FEATURES

All of the devices in the PIC18F1220/1320 family offer nine different oscillator options, allowing users a wide range of choices in developing application hardware. These include:

- Four Crystal modes, using crystals or ceramic resonators.
- Two External Clock modes, offering the option of using two pins (oscillator input and a divide-by-4 clock output), or one pin (oscillator input, with the second pin reassigned as general I/O).
- Two External RC Oscillator modes, with the same pin options as the External Clock modes.
- An internal oscillator block, which provides an 8 MHz clock (±2% accuracy) and an INTRC source (approximately 31 kHz, stable over temperature and VDD), as well as a range of 6 user-selectable clock frequencies (from 125 kHz to 4 MHz) for a total of 8 clock frequencies.

Besides its availability as a clock source, the internal oscillator block provides a stable reference source that gives the family additional features for robust operation:

- Fail-Safe Clock Monitor: This option constantly monitors the main clock source against a reference signal provided by the internal oscillator. If a clock failure occurs, the controller is switched to the internal oscillator block, allowing for continued low-speed operation, or a safe application shutdown.
- **Two-Speed Start-up:** This option allows the internal oscillator to serve as the clock source from Poweron Reset, or wake-up from Sleep mode, until the primary clock source is available. This allows for code execution during what would otherwise be the clock start-up interval and can even allow an application to perform routine background activities and return to Sleep without returning to full power operation.

#### 1.2 Other Special Features

- **Memory Endurance:** The Enhanced Flash cells for both program memory and data EEPROM are rated to last for many thousands of erase/write cycles – up to 100,000 for program memory and 1,000,000 for EEPROM. Data retention without refresh is conservatively estimated to be greater than 40 years.
- Self-programmability: These devices can write to their own program memory spaces under internal software control. By using a bootloader routine located in the protected Boot Block at the top of program memory, it becomes possible to create an application that can update itself in the field.
- Enhanced CCP module: In PWM mode, this module provides 1, 2 or 4 modulated outputs for controlling half-bridge and full-bridge drivers. Other features include auto-shutdown, for disabling PWM outputs on interrupt or other select conditions and auto-restart, to reactivate outputs once the condition has cleared.
- Enhanced USART: This serial communication module features automatic wake-up on Start bit and automatic baud rate detection and supports RS-232, RS-485 and LIN 1.2 protocols, making it ideally suited for use in Local Interconnect Network (LIN) bus applications.
- **10-bit A/D Converter:** This module incorporates programmable acquisition time, allowing for a channel to be selected and a conversion to be initiated without waiting for a sampling period and thus, reduce code overhead.
- Extended Watchdog Timer (WDT): This enhanced version incorporates a 16-bit prescaler, allowing a time-out range from 4 ms to over 2 minutes that is stable across operating voltage and temperature.

#### 1.3 Details on Individual Family Members

Devices in the PIC18F1220/1320 family are available in 18-pin, 20-pin and 28-pin packages. A block diagram for this device family is shown in Figure 1-1.

The devices are differentiated from each other only in the amount of on-chip Flash program memory (4 Kbytes for the PIC18F1220 device, 8 Kbytes for the PIC18F1320 device). These and other features are summarized in Table 1-1. A block diagram of the PIC18F1220/1320 device architecture is provided in Figure 1-1. The pinouts for this device family are listed in Table 1-2.

#### TABLE 1-1:DEVICE FEATURES

## PIC18F1220/1320

NOTES:

#### 2.0 OSCILLATOR CONFIGURATIONS

#### 2.1 Oscillator Types

The PIC18F1220 and PIC18F1320 devices can be operated in ten different oscillator modes. The user can program the configuration bits, FOSC3:FOSC0, in Configuration Register 1H to select one of these ten modes:

- 2. XT Crystal/Resonator
- 3. HS High-Speed Crystal/Resonator
- 4. HSPLL High-Speed Crystal/Resonator with PLL enabled
- 5. RC External Resistor/Capacitor with FOSC/4 output on RA6
- 6. RCIO External Resistor/Capacitor with I/O on RA6
- 7. INTIO1 Internal Oscillator with Fosc/4 output on RA6 and I/O on RA7
- 8. INTIO2 Internal Oscillator with I/O on RA6 and RA7
- 9. EC External Clock with Fosc/4 output
- 10. ECIO External Clock with I/O on RA6

#### 2.2 Crystal Oscillator/Ceramic Resonators

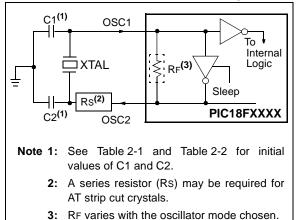

In XT, LP, HS or HSPLL Oscillator modes, a crystal or ceramic resonator is connected to the OSC1 and OSC2 pins to establish oscillation. Figure 2-1 shows the pin connections.

The oscillator design requires the use of a parallel cut crystal.

**Note:** Use of a series cut crystal may give a frequency out of the crystal manufacturer's specifications.

#### FIGURE 2-1:

#### CRYSTAL/CERAMIC RESONATOR OPERATION (XT, LP, HS OR HSPLL CONFIGURATION)

## TABLE 2-1:CAPACITOR SELECTION FOR<br/>CERAMIC RESONATORS

Typical Capacitor Values Used:										
Mode	Mode Freq OSC1 OSC2									
XT	455 kHz	56 pF	56 pF							
	2.0 MHz	47 pF	47 pF							
	4.0 MHz	33 pF	33 pF							
HS	8.0 MHz	27 pF	27 pF							
	16.0 MHz	22 pF	22 pF							

#### Capacitor values are for design guidance only.

These capacitors were tested with the resonators listed below for basic start-up and operation. **These** values are not optimized.

Different capacitor values may be required to produce acceptable oscillator operation. The user should test the performance of the oscillator over the expected VDD and temperature range for the application.

See the notes following Table 2-2 for additional information.

Resonators Used:							
455 kHz 4.0 MHz							
2.0 MHz	8.0 MHz						
16.0 MHz							

### TABLE 2-2:CAPACITOR SELECTION FOR<br/>CRYSTAL OSCILLATOR

Osc Type	Crystal Freq	Typical Capacitor Values Tested:				
	Fieq	C1	C2			
LP	32 kHz	33 pF	33 pF			
	200 kHz	15 pF	15 pF			
XT	1 MHz	33 pF	33 pF			
	4 MHz	27 pF	27 pF			
HS	4 MHz	27 pF	27 pF			
	8 MHz	22 pF	22 pF			
	20 MHz	15 pF	15 pF			

Capacitor values are for design guidance only.

These capacitors were tested with the crystals listed below for basic start-up and operation. **These values are not optimized.** 

Different capacitor values may be required to produce acceptable oscillator operation. The user should test the performance of the oscillator over the expected VDD and temperature range for the application.

See the notes following this table for additional information.

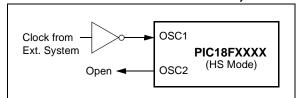

Crystals Used:							
32 kHz	4 MHz						
200 kHz	8 MHz						
1 MHz	20 MHz						

- Note 1: Higher capacitance increases the stability of oscillator, but also increases the start-up time.
  - 2: When operating below 3V VDD, or when using certain ceramic resonators at any voltage, it may be necessary to use the HS mode or switch to a crystal oscillator.
  - Since each resonator/crystal has its own characteristics, the user should consult the resonator/crystal manufacturer for appropriate values of external components.
  - 4: Rs may be required to avoid overdriving crystals with low drive level specification.
  - Always verify oscillator performance over the VDD and temperature range that is expected for the application.

An external clock source may also be connected to the OSC1 pin in the HS mode, as shown in Figure 2-2.

#### EXTERNAL CLOCK INPUT OPERATION (HS OSC CONFIGURATION)

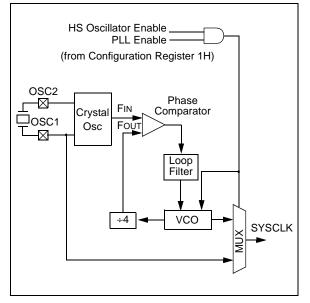

#### 2.3 HSPLL

A Phase Locked Loop (PLL) circuit is provided as an option for users who wish to use a lower frequency crystal oscillator circuit, or to clock the device up to its highest rated frequency from a crystal oscillator. This may be useful for customers who are concerned with EMI due to high-frequency crystals.

The HSPLL mode makes use of the HS mode oscillator for frequencies up to 10 MHz. A PLL then multiplies the oscillator output frequency by 4 to produce an internal clock frequency up to 40 MHz.

The PLL is enabled only when the oscillator configuration bits are programmed for HSPLL mode. If programmed for any other mode, the PLL is not enabled.

#### FIGURE 2-3: PLL BLOCK DIAGRAM

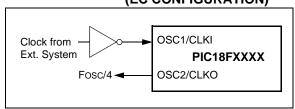

#### 2.4 External Clock Input

The EC and ECIO Oscillator modes require an external clock source to be connected to the OSC1 pin. There is no oscillator start-up time required after a Power-on Reset, or after an exit from Sleep mode.

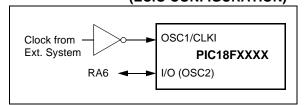

In the EC Oscillator mode, the oscillator frequency divided by 4 is available on the OSC2 pin. This signal may be used for test purposes, or to synchronize other logic. Figure 2-4 shows the pin connections for the EC Oscillator mode.

#### FIGURE 2-4: EXTERNAL CLOCK INPUT OPERATION (EC CONFIGURATION)

The ECIO Oscillator mode functions like the EC mode, except that the OSC2 pin becomes an additional general purpose I/O pin. The I/O pin becomes bit 6 of PORTA (RA6). Figure 2-5 shows the pin connections for the ECIO Oscillator mode.

#### FIGURE 2-5: EXTERNAL CLOCK INPUT OPERATION (ECIO CONFIGURATION)

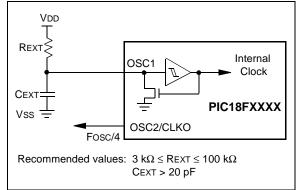

#### 2.5 RC Oscillator

For timing insensitive applications, the "RC" and "RCIO" device options offer additional cost savings. The RC oscillator frequency is a function of the supply voltage, the resistor (REXT) and capacitor (CEXT) values and the operating temperature. In addition to this, the oscillator frequency will vary from unit to unit due to normal manufacturing variation. Furthermore, the difference in lead frame capacitance between package types will also affect the oscillation frequency, especially for low CEXT values. The user also needs to take into account variation, due to tolerance of external R and C components used. Figure 2-6 shows how the R/C combination is connected.

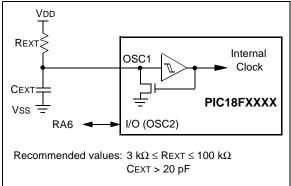

In the RC Oscillator mode, the oscillator frequency divided by 4 is available on the OSC2 pin. This signal may be used for test purposes, or to synchronize other logic.

The RCIO Oscillator mode (Figure 2-7) functions like the RC mode, except that the OSC2 pin becomes an additional general purpose I/O pin. The I/O pin becomes bit 6 of PORTA (RA6).

#### 2.6 Internal Oscillator Block

The PIC18F1220/1320 devices include an internal oscillator block, which generates two different clock signals; either can be used as the system's clock source. This can eliminate the need for external oscillator circuits on the OSC1 and/or OSC2 pins.

The main output (INTOSC) is an 8 MHz clock source, which can be used to directly drive the system clock. It also drives a postscaler, which can provide a range of clock frequencies from 125 kHz to 4 MHz. The INTOSC output is enabled when a system clock frequency from 125 kHz to 8 MHz is selected.

The other clock source is the internal RC oscillator (INTRC), which provides a 31 kHz output. The INTRC oscillator is enabled by selecting the internal oscillator block as the system clock source, or when any of the following are enabled:

- Power-up Timer
- Fail-Safe Clock Monitor
- Watchdog Timer
- Two-Speed Start-up

These features are discussed in greater detail in **Section 19.0 "Special Features of the CPU"**.

The clock source frequency (INTOSC direct, INTRC direct or INTOSC postscaler) is selected by configuring the IRCF bits of the OSCCON register (Register 2-2).

#### 2.6.1 INTIO MODES

Using the internal oscillator as the clock source can eliminate the need for up to two external oscillator pins, which can then be used for digital I/O. Two distinct configurations are available:

- In INTIO1 mode, the OSC2 pin outputs Fosc/4, while OSC1 functions as RA7 for digital input and output.
- In INTIO2 mode, OSC1 functions as RA7 and OSC2 functions as RA6, both for digital input and output.

#### 2.6.2 INTRC OUTPUT FREQUENCY

The internal oscillator block is calibrated at the factory to produce an INTOSC output frequency of 8.0 MHz (see Table 22-6). This changes the frequency of the INTRC source from its nominal 31.25 kHz. Peripherals and features that depend on the INTRC source will be affected by this shift in frequency.

Once set during factory calibration, the INTRC frequency will remain within  $\pm 2\%$  as temperature and VDD change across their full specified operating ranges.

#### 2.6.3 OSCTUNE REGISTER

The internal oscillator's output has been calibrated at the factory, but can be adjusted in the user's application. This is done by writing to the OSCTUNE register (Register 2-1). The tuning sensitivity is constant throughout the tuning range.

When the OSCTUNE register is modified, the INTOSC and INTRC frequencies will begin shifting to the new frequency. The INTRC clock will reach the new frequency within 8 clock cycles (approximately  $8 * 32 \ \mu\text{s} = 256 \ \mu\text{s}$ ). The INTOSC clock will stabilize within 1 ms. Code execution continues during this shift. There is no indication that the shift has occurred. Operation of features that depend on the INTRC clock source frequency, such as the WDT, Fail-Safe Clock Monitor and peripherals, will also be affected by the change in frequency.

#### OSCILINE: OSCILLATOR TUNING REGISTER

#### 2.7 Clock Sources and Oscillator Switching

Like previous PIC18 devices, the PIC18F1220/1320 devices include a feature that allows the system clock source to be switched from the main oscillator to an alternate low-frequency clock source. PIC18F1220/ 1320 devices offer two alternate clock sources. When enabled, these give additional options for switching to the various power managed operating modes.

-n = Value at POR

Essentially, there are three clock sources for these devices:

- Primary oscillators
- Secondary oscillators
- Internal oscillator block

The primary oscillators include the External Crystal and Resonator modes, the External RC modes, the External Clock modes and the internal oscillator block. The particular mode is defined on POR by the contents of Configuration Register 1H. The details of these modes are covered earlier in this chapter.

The **secondary oscillators** are those external sources not connected to the OSC1 or OSC2 pins. These sources may continue to operate even after the controller is placed in a power managed mode.

PIC18F1220/1320 devices offer only the Timer1 oscillator as a secondary oscillator. This oscillator, in all power managed modes, is often the time base for functions such as a real-time clock.

x = Bit is unknown

'0' = Bit is cleared

Most often, a 32.768 kHz watch crystal is connected between the RB6/T1OSO and RB7/T1OSI pins. Like the LP mode oscillator circuit, loading capacitors are also connected from each pin to ground. These pins are also used during ICSP operations.

The Timer1 oscillator is discussed in greater detail in Section 12.2 "Timer1 Oscillator".

In addition to being a primary clock source, the internal oscillator block is available as a power managed mode clock source. The INTRC source is also used as the clock source for several special features, such as the WDT and Fail-Safe Clock Monitor.

The clock sources for the PIC18F1220/1320 devices are shown in Figure 2-8. See Section 12.0 "Timer1 Module" for further details of the Timer1 oscillator. See Section 19.1 "Configuration Bits" for configuration register details.

#### 2.7.1 OSCILLATOR CONTROL REGISTER

The OSCCON register (Register 2-2) controls several aspects of the system clock's operation, both in full power operation and in power managed modes.

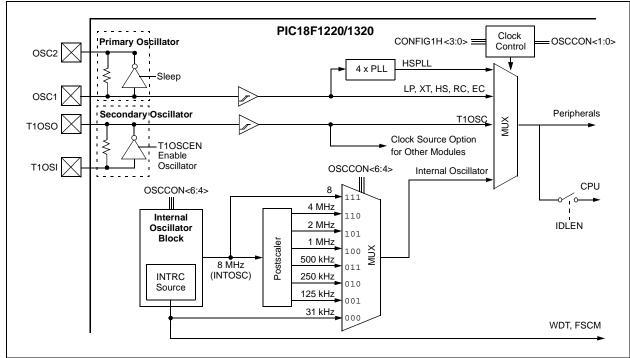

The System Clock Select bits, SCS1:SCS0, select the clock source that is used when the device is operating in power managed modes. The available clock sources are the primary clock (defined in Configuration Register 1H), the secondary clock (Timer1 oscillator) and the internal oscillator block. The clock selection has no effect until a SLEEP instruction is executed and the device enters a power managed mode of operation. The SCS bits are cleared on all forms of Reset.

The Internal Oscillator Select bits, IRCF2:IRCF0, select the frequency output of the internal oscillator block that is used to drive the system clock. The choices are the INTRC source, the INTOSC source (8 MHz), or one of the six frequencies derived from the INTOSC postscaler (125 kHz to 4 MHz). If the internal oscillator block is supplying the system clock, changing the states of these bits will have an immediate change on the internal oscillator's output.

The OSTS, IOFS and T1RUN bits indicate which clock source is currently providing the system clock. The OSTS indicates that the Oscillator Start-up Timer has timed out and the primary clock is providing the system clock in Primary Clock modes. The IOFS bit indicates when the internal oscillator block has stabilized and is providing the system clock in RC Clock modes or during Two-Speed Start-ups. The T1RUN bit (T1CON<6>) indicates when the Timer1 oscillator is providing the system clock in Secondary Clock modes. In power managed modes, only one of these three bits will be set at any time. If none of these bits are set, the INTRC is providing the system clock, or the internal oscillator block has just started and is not yet stable.

The IDLEN bit controls the selective shutdown of the controller's CPU in power managed modes. The uses of these bits are discussed in more detail in **Section 3.0 "Power Managed Modes"**.

- Note 1: The Timer1 oscillator must be enabled to select the secondary clock source. The Timer1 oscillator is enabled by setting the T1OSCEN bit in the Timer1 Control register (T1CON<3>). If the Timer1 oscillator is not enabled, then any attempt to select a secondary clock source when executing a SLEEP instruction will be ignored.
  - 2: It is recommended that the Timer1 oscillator be operating and stable before executing the SLEEP instruction or a very long delay may occur while the Timer1 oscillator starts.

#### 2.7.2 OSCILLATOR TRANSITIONS

The PIC18F1220/1320 devices contain circuitry to prevent clocking "glitches" when switching between clock sources. A short pause in the system clock occurs during the clock switch. The length of this pause is between 8 and 9 clock periods of the new clock source. This ensures that the new clock source is stable and that its pulse width will not be less than the shortest pulse width of the two clock sources.

Clock transitions are discussed in greater detail in **Section 3.1.2 "Entering Power Managed Modes"**.

#### 2.8 Effects of Power Managed Modes on the Various Clock Sources

When the device executes a SLEEP instruction, the system is switched to one of the power managed modes, depending on the state of the IDLEN and SCS1:SCS0 bits of the OSCCON register. See Section 3.0 "Power Managed Modes" for details.

When PRI\_IDLE mode is selected, the designated primary oscillator continues to run without interruption. For all other power managed modes, the oscillator using the OSC1 pin is disabled. The OSC1 pin (and OSC2 pin, if used by the oscillator) will stop oscillating.

In Secondary Clock modes (SEC\_RUN and SEC\_IDLE), the Timer1 oscillator is operating and providing the system clock. The Timer1 oscillator may also run in all power managed modes if required to clock Timer1 or Timer3.

In Internal Oscillator modes (RC\_RUN and RC\_IDLE), the internal oscillator block provides the system clock source. The INTRC output can be used directly to provide the system clock and may be enabled to support various special features, regardless of the power managed mode (see Section 19.2 "Watchdog Timer (WDT)" through Section 19.4 "Fail-Safe Clock Monitor"). The INTOSC output at 8 MHz may be used directly to clock the system, or may be divided down first. The INTOSC output is disabled if the system clock is provided directly from the INTRC output. If the Sleep mode is selected, all clock sources are stopped. Since all the transistor switching currents have been stopped, Sleep mode achieves the lowest current consumption of the device (only leakage currents).

Enabling any on-chip feature that will operate during Sleep will increase the current consumed during Sleep. The INTRC is required to support WDT operation. The Timer1 oscillator may be operating to support a realtime clock. Other features may be operating that do not require a system clock source (i.e., INTn pins, A/D conversions and others).

#### 2.9 Power-up Delays

Power-up delays are controlled by two timers, so that no external Reset circuitry is required for most applications. The delays ensure that the device is kept in Reset until the device power supply is stable under normal circumstances and the primary clock is operating and stable. For additional information on power-up delays, see Sections 4.1 through 4.5.

The first timer is the Power-up Timer (PWRT), which provides a fixed delay on power-up (parameter 33, Table 22-8) if enabled in Configuration Register 2L. The second timer is the Oscillator Start-up Timer (OST), intended to keep the chip in Reset until the crystal oscillator is stable (LP, XT and HS modes). The OST does this by counting 1024 oscillator cycles before allowing the oscillator to clock the device.

When the HSPLL Oscillator mode is selected, the device is kept in Reset for an additional 2 ms following the HS mode OST delay, so the PLL can lock to the incoming clock frequency.

There is a delay of 5 to 10  $\mu s$  following POR while the controller becomes ready to execute instructions. This delay runs concurrently with any other delays. This may be the only delay that occurs when any of the EC, RC or INTIO modes are used as the primary clock source.

Oscillator Mode	OSC1 Pin	OSC2 Pin
RC, INTIO1	Floating, external resistor should pull high	At logic low (clock/4 output)
RCIO, INTIO2	Floating, external resistor should pull high	Configured as PORTA, bit 6
ECIO	Floating, pulled by external clock	Configured as PORTA, bit 6
EC	Floating, pulled by external clock	At logic low (clock/4 output)
LP, XT and HS	Feedback inverter disabled at quiescent voltage level	Feedback inverter disabled at quiescent voltage level

TABLE 2-3:OSC1 AND OSC2 PIN STATES IN SLEEP MODE

**Note:** See Table 4-1 in **Section 4.0** "**Reset**" for time-outs due to Sleep and MCLR Reset.

#### 3.0 POWER MANAGED MODES

The PIC18F1220/1320 devices offer a total of six operating modes for more efficient power management (see Table 3-1). These provide a variety of options for selective power conservation in applications where resources may be limited (i.e., battery powered devices).

There are three categories of power managed modes:

- Sleep mode
- Idle modes
- Run modes

These categories define which portions of the device are clocked and sometimes, what speed. The Run and Idle modes may use any of the three available clock sources (primary, secondary or INTOSC multiplexer); the Sleep mode does not use a clock source.

The clock switching feature offered in other PIC18 devices (i.e., using the Timer1 oscillator in place of the primary oscillator) and the Sleep mode offered by all PICmicro<sup>®</sup> devices (where all system clocks are stopped) are both offered in the PIC18F1220/1320 devices (SEC\_RUN and Sleep modes, respectively). However, additional power managed modes are available that allow the user greater flexibility in determining what portions of the device are operating. The power managed modes are event driven; that is, some specific event must occur for the device to enter or (more particularly) exit these operating modes.

For PIC18F1220/1320 devices, the power managed modes are invoked by using the existing SLEEP instruction. All modes exit to PRI\_RUN mode when triggered by an interrupt, a Reset or a WDT time-out (PRI\_RUN mode is the normal full power execution mode; the CPU and peripherals are clocked by the primary oscillator source). In addition, power managed Run modes may also exit to Sleep mode, or their corresponding Idle mode.

#### 3.1 Selecting Power Managed Modes

Selecting a power managed mode requires deciding if the CPU is to be clocked or not and selecting a clock source. The IDLEN bit controls CPU clocking, while the SCS1:SCS0 bits select a clock source. The individual modes, bit settings, clock sources and affected modules are summarized in Table 3-1.

#### 3.1.1 CLOCK SOURCES

The clock source is selected by setting the SCS bits of the OSCCON register (Register 2-2). Three clock sources are available for use in power managed Idle modes: the primary clock (as configured in Configuration Register 1H), the secondary clock (Timer1 oscillator) and the internal oscillator block. The secondary and internal oscillator block sources are available for the power managed modes (PRI\_RUN mode is the normal full power execution mode; the CPU and peripherals are clocked by the primary oscillator source).

	OSCCON Bits		Module Clocking			
Mode IDLEN SCS1:SCS0 <7> <1:0> CPU Peripherals		Available Clock and Oscillator Source				
Sleep	0	00	Off	Off	None – All clocks are disabled	
PRI_RUN	0	00	Clocked	Clocked	Primary – LP, XT, HS, HSPLL, RC, EC, INTRC <sup>(1)</sup> This is the normal full power execution mode.	
SEC_RUN	0	01	Clocked	Clocked	Secondary – Timer1 Oscillator	
RC_RUN	0	1x	Clocked	Clocked	Internal Oscillator Block <sup>(1)</sup>	
PRI_IDLE	1	00	Off	Clocked	Primary – LP, XT, HS, HSPLL, RC, EC	
SEC_IDLE	1	01	Off	Clocked	Secondary – Timer1 Oscillator	
RC_IDLE	1	1x	Off	Clocked	Internal Oscillator Block <sup>(1)</sup>	

TABLE 3-1: POWER MANAGED MODES

Note 1: Includes INTOSC and INTOSC postscaler, as well as the INTRC source.

#### 3.1.2 ENTERING POWER MANAGED MODES

In general, entry, exit and switching between power managed clock sources requires clock source switching. In each case, the sequence of events is the same.

Any change in the power managed mode begins with loading the OSCCON register and executing a SLEEP instruction. The SCS1:SCS0 bits select one of three power managed clock sources; the primary clock (as defined in Configuration Register 1H), the secondary clock (the Timer1 oscillator) and the internal oscillator block (used in RC modes). Modifying the SCS bits will have no effect until a SLEEP instruction is executed. Entry to the power managed mode is triggered by the execution of a SLEEP instruction.

Figure 3-5 shows how the system is clocked while switching from the primary clock to the Timer1 oscillator. When the SLEEP instruction is executed, clocks to the device are stopped at the beginning of the next instruction cycle. Eight clock cycles from the new clock source are counted to synchronize with the new clock source are counted, clocks from the new clock source are counted, clocks from the new clock source are counted, clocks from the new clock source resume clocking the system. The actual length of the pause is between eight and nine clock periods from the new clock source. This ensures that the new clock source is stable and that its pulse width will not be less than the shortest pulse width of the two clock sources.

Three bits indicate the current clock source: OSTS and IOFS in the OSCCON register and T1RUN in the T1CON register. Only one of these bits will be set while in a power managed mode. When the OSTS bit is set, the primary clock is providing the system clock. When the IOFS bit is set, the INTOSC output is providing a stable 8 MHz clock source and is providing the system clock. When the T1RUN bit is set, the Timer1 oscillator is providing the system clock. If none of these bits are set, then either the INTRC clock source is clocking the system, or the INTOSC source is not yet stable.

If the internal oscillator block is configured as the primary clock source in Configuration Register 1H, then both the OSTS and IOFS bits may be set when in PRI\_RUN or PRI\_IDLE modes. This indicates that the primary clock (INTOSC output) is generating a stable 8 MHz output. Entering an RC power managed mode (same frequency) would clear the OSTS bit.

#### 3.1.3 MULTIPLE SLEEP COMMANDS

The power managed mode that is invoked with the SLEEP instruction is determined by the settings of the IDLEN and SCS bits at the time the instruction is executed. If another SLEEP instruction is executed, the device will enter the power managed mode specified by these same bits at that time. If the bits have changed, the device will enter the new power managed mode specified by the new bit settings.

#### 3.1.4 COMPARISONS BETWEEN RUN AND IDLE MODES

Clock source selection for the Run modes is identical to the corresponding Idle modes. When a SLEEP instruction is executed, the SCS bits in the OSCCON register are used to switch to a different clock source. As a result, if there is a change of clock source at the time a SLEEP instruction is executed, a clock switch will occur.

In Idle modes, the CPU is not clocked and is not running. In Run modes, the CPU is clocked and executing code. This difference modifies the operation oe.1TJ/F7-0.9(.4ng)13I1(c

Power Managed Mode	CPU is Clocked by	WDT Time-out causes a	Peripherals are Clocked by	Clock during Wake-up (while primary becomes ready)
Sleep	Not clocked (not running)	Wake-up	Not clocked	None or INTOSC multiplexer if Two-Speed Start-up or Fail-Safe Clock Monitor are enabled
Any Idle mode	Not clocked (not running)	Wake-up	Primary, Secondary or INTOSC multiplexer	Unchanged from Idle mode (CPU operates as in corresponding Run mode)
Any Run mode	Primary or secondary clocks or INTOSC multiplexer	Reset	Primary or secondary clocks or INTOSC multiplexer	Unchanged from Run mode

TABLE 3-2: COMPARISON BETWEEN POWER MANAGED MODES

#### 3.2 Sleep Mode

The power managed Sleep mode in the PIC18F1220/ 1320 devices is identical to that offered in all other PICmicro microcontrollers. It is entered by clearing the IDLEN and SCS1:SCS0 bits (this is the Reset state) and executing the SLEEP instruction. This shuts down the primary oscillator and the OSTS bit is cleared (see Figure 3-1).

When a wake event occurs in Sleep mode (by interrupt, Reset or WDT time-out), the system will not be clocked until the primary clock source becomes ready (see Figure 3-2), or it will be clocked from the internal oscillator block if either the Two-Speed Start-up or the Fail-Safe Clock Monitor are enabled (see **Section 19.0 "Special Features of the CPU"**). In either case, the OSTS bit is set when the primary clock is providing the system clocks. The IDLEN and SCS bits are not affected by the wake-up.

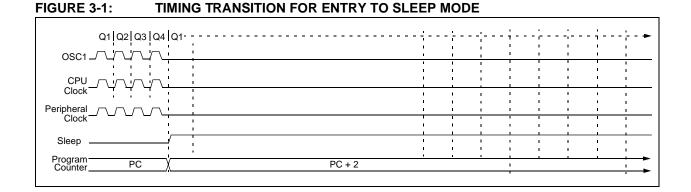

#### 3.3 Idle Modes

The IDLEN bit allows the microcontroller's CPU to be selectively shut down while the peripherals continue to operate. Clearing IDLEN allows the CPU to be clocked. Setting IDLEN disables clocks to the CPU, effectively stopping program execution (see Register 2-2). The peripherals continue to be clocked regardless of the setting of the IDLEN bit.

There is one exception to how the IDLEN bit functions. When all the low-power OSCCON bits are cleared (IDLEN:SCS1:SCS0 = 000), the device enters Sleep mode upon the execution of the SLEEP instruction. This is both the Reset state of the OSCCON register and the setting that selects Sleep mode. This maintains compatibility with other PICmicro devices that do not offer power managed modes. If the Idle Enable bit, IDLEN (OSCCON<7>), is set to a '1' when a SLEEP instruction is executed, the peripherals will be clocked from the clock source selected using the SCS1:SCS0 bits; however, the CPU will not be clocked. Since the CPU is not executing instructions, the only exits from any of the Idle modes are by interrupt, WDT time-out or a Reset.

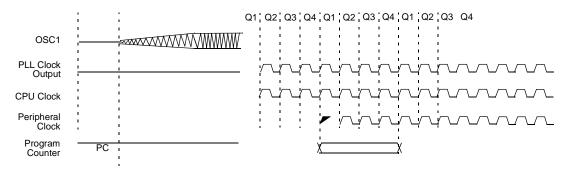

When a wake event occurs, CPU execution is delayed approximately 10  $\mu$ s while it becomes ready to execute code. When the CPU begins executing code, it is clocked by the same clock source as was selected in the power managed mode (i.e., when waking from RC\_IDLE mode, the internal oscillator block will clock the CPU and peripherals until the primary clock source becomes ready – this is essentially RC\_RUN mode). This continues until the primary clock source becomes ready. When the primary clock becomes ready, the OSTS bit is set and the system clock source is switched to the primary clock (see Figure 3-4). The IDLEN and SCS bits are not affected by the wake-up.

While in any Idle mode or the Sleep mode, a WDT time-out will result in a WDT wake-up to full power operation.

#### TRANSITION TIMING FOR WAKE FROM SLEEP (HSPLL)

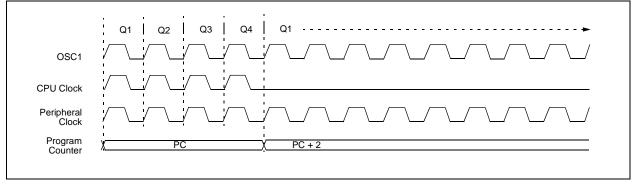

#### 3.3.1 PRI\_IDLE MODE

This mode is unique among the three Low-Power Idle modes, in that it does not disable the primary system clock. For timing sensitive applications, this allows for the fastest resumption of device operation with its more accurate primary clock source, since the clock source does not have to "warm up" or transition from another oscillator.

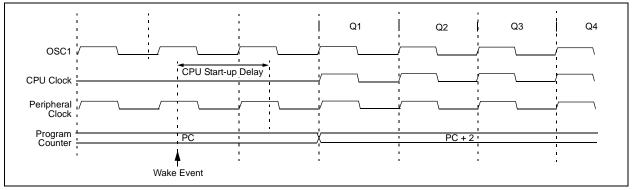

PRI\_IDLE mode is entered by setting the IDLEN bit, clearing the SCS bits and executing a SLEEP instruction. Although the CPU is disabled, the peripherals continue to be clocked from the primary clock source specified in Configuration Register 1H. The OSTS bit remains set in PRI\_IDLE mode (see Figure 3-3).

When a wake event occurs, the CPU is clocked from the primary clock source. A delay of approximately 10  $\mu$ s is required between the wake event and code execution starts. This is required to allow the CPU to become ready to execute instructions. After the wakeup, the OSTS bit remains set. The IDLEN and SCS bits are not affected by the wake-up (see Figure 3-4).

#### FIGURE 3-3: TRANSITION TIMING TO PRI\_IDLE MODE

#### FIGURE 3-4: TRANSITION TIMING FOR WAKE FROM PRI\_IDLE MODE

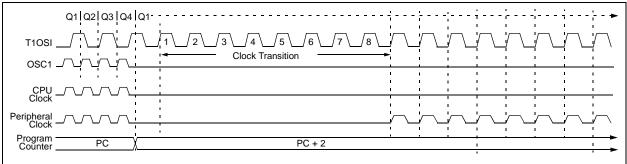

#### 3.3.2 SEC\_IDLE MODE

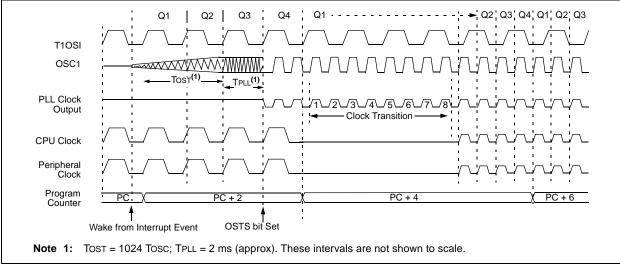

In SEC\_IDLE mode, the CPU is disabled, but the peripherals continue to be clocked from the Timer1 oscillator. This mode is entered by setting the Idle bit, modifying bits, SCS1:SCS0 = 01 and executing a SLEEP instruction. When the clock source is switched (see Figure 3-5) to the Timer1 oscillator, the primary oscillator is shut down, the OSTS bit is cleared and the T1RUN bit is set.

Note: The Timer1 oscillator should already be running prior to entering SEC\_IDLE mode. If the T1OSCEN bit is not set when the SLEEP instruction is executed, the SLEEP instruction will be ignored and entry to SEC\_IDLE mode will not occur. If the Timer1 oscillator is enabled, but not yet running, peripheral clocks will be delayed until the oscillator has started; in such situations, initial oscillator operation is far from stable and unpredictable operation may result. When a wake event occurs, the peripherals continue to be clocked from the Timer1 oscillator. After a  $10 \,\mu s$ delay following the wake event, the CPU begins executing code, being clocked by the Timer1 oscillator. The microcontroller operates in SEC\_RUN mode until the primary clock becomes ready. When the primary clock becomes ready, a clock switchback to the primary clock occurs (see Figure 3-6). When the clock switch is complete, the T1RUN bit is cleared, the OSTS bit is set and the primary clock is providing the system clock. The IDLEN and SCS bits are not affected by the wake-up. The Timer1 oscillator continues to run.

#### FIGURE 3-5: TIMING TRANSITION FOR ENTRY TO SEC\_IDLE MODE

#### 3.3.3 RC\_IDLE MODE

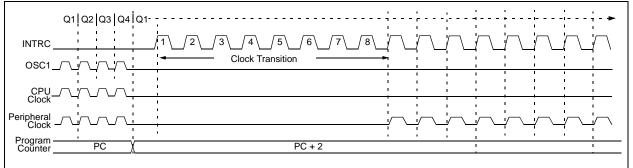

In RC\_IDLE mode, the CPU is disabled, but the peripherals continue to be clocked from the internal oscillator block using the INTOSC multiplexer. This mode allows for controllable power conservation during Idle periods.

This mode is entered by setting the IDLEN bit, setting SCS1 (SCS0 is ignored) and executing a SLEEP instruction. The INTOSC multiplexer may be used to select a higher clock frequency by modifying the IRCF bits before executing the SLEEP instruction. When the clock source is switched to the INTOSC multiplexer (see Figure 3-7), the primary oscillator is shut down and the OSTS bit is cleared.

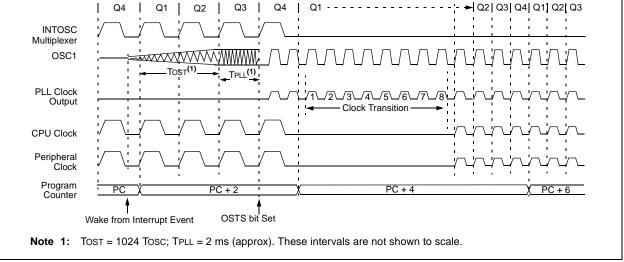

If the IRCF bits are set to a non-zero value (thus, enabling the INTOSC output), the IOFS bit becomes set after the INTOSC output becomes stable, in about 1 ms. Clocks to the peripherals continue while the INTOSC source stabilizes. If the IRCF bits were previously at a non-zero value before the SLEEP instruction was executed and the INTOSC source was already stable, the IOFS bit will remain set. If the IRCF bits are all clear, the INTOSC output is not enabled and the IOFS bit will remain clear; there will be no indication of the current clock source.

When a wake event occurs, the peripherals continue to be clocked from the INTOSC multiplexer. After a 10  $\mu$ s delay following the wake event, the CPU begins executing code, being clocked by the INTOSC multiplexer. The microcontroller operates in RC\_RUN mode until the primary clock becomes ready. When the primary clock becomes ready, a clock switchback to the primary clock occurs (see Figure 3-8). When the clock switch is complete, the IOFS bit is cleared, the OSTS bit is set and the primary clock is providing the system clock. The IDLEN and SCS bits are not affected by the wakeup. The INTRC source will continue to run if either the WDT or the Fail-Safe Clock Monitor is enabled.

#### 3.4 Run Modes

If the IDLEN bit is clear when a SLEEP instruction is executed, the CPU and peripherals are both clocked from the source selected using the SCS1:SCS0 bits. While these operating modes may not afford the power conservation of Idle or Sleep modes, they do allow the device to continue executing instructions by using a lower frequency clock source. RC\_RUN mode also offers the possibility of executing code at a frequency greater than the primary clock.

Wake-up from a power managed Run mode can be triggered by an interrupt, or any Reset, to return to full power operation. As the CPU is executing code in Run modes, several additional exits from Run modes are possible. They include exit to Sleep mode, exit to a corresponding Idle mode and exit by executing a RESET instruction. While the device is in any of the power managed Run modes, a WDT time-out will result in a WDT Reset.

#### 3.4.1 PRI\_RUN MODE

The PRI\_RUN mode is the normal full power execution mode. If the SLEEP instruction is never executed, the microcontroller operates in this mode (a SLEEP instruction is executed to enter all other power managed modes). All other power managed modes exit to PRI\_RUN mode when an interrupt or WDT time-out occur.

There is no entry to PRI\_RUN mode. The OSTS bit is set. The IOFS bit may be set if the internal oscillator block is the primary clock source (see **Section 2.7.1** "Oscillator Control Register").

#### 3.4.2 SEC\_RUN MODE

The SEC\_RUN mode is the compatible mode to the "clock switching" feature offered in other PIC18 devices. In this mode, the CPU and peripherals are clocked from the Timer1 oscillator. This gives users the option of lower power consumption while still using a high accuracy clock source.

SEC\_RUN mode is entered by clearing the IDLEN bit, setting SCS1:SCS0 = 01 and executing a SLEEP instruction. The system clock source is switched to the Timer1 oscillator (see Figure 3-9), the primary oscillator is shut down, the T1RUN bit (T1CON<6>) is set and the OSTS bit is cleared.

Note: The Timer1 oscillator should already be running prior to entering SEC\_RUN mode. If the T1OSCEN bit is not set when the SLEEP instruction is executed, the SLEEP instruction will be ignored and entry to SEC\_RUN mode will not occur. If the Timer1 oscillator is enabled, but not yet running, system clocks will be delayed until the oscillator has started; in such situations, initial oscillator operation is far from stable and unpredictable operation may result.

When a wake event occurs, the peripherals and CPU continue to be clocked from the Timer1 oscillator while the primary clock is started. When the primary clock becomes ready, a clock switchback to the primary clock occurs (see Figure 3-6). When the clock switch is complete, the T1RUN bit is cleared, the OSTS bit is set and the primary clock is providing the system clock. The IDLEN and SCS bits are not affected by the wake-up. The Timer1 oscillator continues to run.

Firmware can force an exit from SEC\_RUN mode. By clearing the T1OSCEN bit (T1CON<3>), an exit from SEC\_RUN back to normal full power operation is triggered. The Timer1 oscillator will continue to run and provide the system clock, even though the T1OSCEN bit is cleared. The primary clock is started. When the primary clock becomes ready, a clock switchback to the primary clock occurs (see Figure 3-6). When the clock switch is cleared, the Timer1 oscillator is disabled, the T1RUN bit is cleared, the OSTS bit is set and the primary clock is providing the system clock. The IDLEN and SCS bits are not affected by the wake-up.

#### FIGURE 3-9: TIMING TRANSITION FOR ENTRY TO SEC RUN MODE

#### 3.4.3 RC\_RUN MODE

In RC\_RUN mode, the CPU and peripherals are clocked from the internal oscillator block using the INTOSC multiplexer and the primary clock is shut down. When using the INTRC source, this mode provides the best power conservation of all the Run modes, while still executing code. It works well for user applications which are not highly timing sensitive, or do not require high-speed clocks at all times.

If the primary clock source is the internal oscillator block (either of the INTIO1 or INTIO2 oscillators), there are no distinguishable differences between PRI\_RUN and RC\_RUN modes during execution. However, a clock switch delay will occur during entry to and exit from RC\_RUN mode. Therefore, if the primary clock source is the internal oscillator block, the use of RC\_RUN mode is not recommended.

This mode is entered by clearing the IDLEN bit, setting SCS1 (SCS0 is ignored) and executing a SLEEP instruction. The IRCF bits may select the clock frequency before the SLEEP instruction is executed. When the clock source is switched to the INTOSC multiplexer (see Figure 3-10), the primary oscillator is shut down and the OSTS bit is cleared.

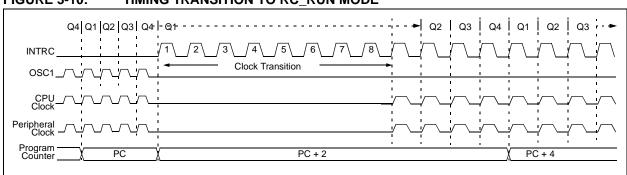

The IRCF bits may be modified at any time to immediately change the system clock speed. Executing a SLEEP instruction is not required to select a new clock frequency from the INTOSC multiplexer. Note: Caution should be used when modifying a single IRCF bit. If VDD is less than 3V, it is possible to select a higher clock speed than is supported by the low VDD. Improper device operation may result if the VDD/Fosc specifications are violated.

If the IRCF bits are all clear, the INTOSC output is not enabled and the IOFS bit will remain clear; there will be no indication of the current clock source. The INTRC source is providing the system clocks.

If the IRCF bits are changed from all clear (thus, enabling the INTOSC output), the IOFS bit becomes set after the INTOSC output becomes stable. Clocks to the system continue while the INTOSC source stabilizes, in approximately 1 ms.

If the IRCF bits were previously at a non-zero value before the SLEEP instruction was executed and the INTOSC source was already stable, the IOFS bit will remain set.

When a wake event occurs, the system continues to be clocked from the INTOSC multiplexer while the primary clock is started. When the primary clock becomes ready, a clock switch to the primary clock occurs (see Figure 3-8). When the clock switch is complete, the IOFS bit is cleared, the OSTS bit is set and the primary clock is providing the system clock. The IDLEN and SCS bits are not affected by the wake-up. The INTRC source will continue to run if either the WDT or the Fail-Safe Clock Monitor is enabled.

#### FIGURE 3-10: TIMING TRANSITION TO RC\_RUN MODE

#### 3.4.4 EXIT TO IDLE MODE

An exit from a power managed Run mode to its corresponding Idle mode is executed by setting the IDLEN bit and executing a SLEEP instruction. The CPU is halted at the beginning of the instruction following the SLEEP instruction. There are no changes to any of the clock source status bits (OSTS, IOFS or T1RUN). While the CPU is halted, the peripherals continue to be clocked from the previously selected clock source.

#### 3.4.5 EXIT TO SLEEP MODE

An exit from a power managed Run mode to Sleep mode is executed by clearing the IDLEN and SCS1:SCS0 bits and executing a SLEEP instruction. The code is no different than the method used to invoke Sleep mode from the normal operating (full power) mode.

The primary clock and internal oscillator block are disabled. The INTRC will continue to operate if the WDT is enabled. The Timer1 oscillator will continue to run, if enabled in the T1CON register (Register 12-1). All clock source status bits are cleared (OSTS, IOFS and T1RUN).

#### 3.5 Wake from Power Managed Modes

An exit from any of the power managed modes is triggered by an interrupt, a Reset or a WDT time-out. This section discusses the triggers that cause exits from power managed modes. The clocking subsystem actions are discussed in each of the power managed modes (see Sections 3.2 through 3.4).

Note:	If application code is timing sensitive, it
	should wait for the OSTS bit to become set
	before continuing. Use the interval during
	the low-power exit sequence (before
	OSTS is set) to perform timing insensitive
	"housekeeping" tasks.

Device behavior during Low-Power mode exits is summarized in Table 3-3.

#### 3.5.1 EXIT BY INTERRUPT

Any of the available interrupt sources can cause the device to exit a power managed mode and resume full power operation. To enable this functionality, an interrupt source must be enabled by setting its enable bit in one of the INTCON or PIE registers. The exit sequence is initiated when the corresponding interrupt flag bit is set. On all exits from Low-Power mode by interrupt, code execution branches to the interrupt vector if the GIE/GIEH bit (INTCON<7>) is set. Otherwise, code execution continues or resumes without branching (see Section 9.0 "Interrupts").

## TABLE 3-3:ACTIVITY AND EXIT DELAY ON WAKE FROM SLEEP MODE OR ANY IDLE MODE<br/>(BY CLOCK SOURCES)

Clock in Power	Primary System	Power Managed	Clock Ready Status Bit (OSCCON)	Activity during Wake-up from Power Managed Mode		
Managed Mode	Clock	Mode Exit Delay		Exit by Interrupt	Exit by Reset	
	LP, XT, HS			clocked by primary	Not clocked or Two-Speed Start-up (if enabled) <sup>(3)</sup> .	
Primary System Clock	HSPLL	5-10 μs <b><sup>(5)</sup></b>				
(PRI_IDLE mode)	EC, RC, INTRC <sup>(1)</sup>	5-10 µs. 7				
(****_** == *******)	INTOSC <sup>(2)</sup>		IOFS			
	LP, XT, HS	OST		CPU and peripherals clocked by selected power managed mode clock and executing		
T1OSC or	HSPLL	OST + 2 ms				
INTRC <sup>(1)</sup>	EC, RC, INTRC <sup>(1)</sup>	5-10 μs <b><sup>(5)</sup></b>	—			
	INTOSC <sup>(2)</sup>	1 ms <sup>(4)</sup>	IOFS	instructions until

	EC, RC, INTRC <sup>(1)</sup>	5-10 μs <b>(5)</b>	—			
	INTOSC <sup>(2)</sup>	None	IOFS			
Sleep mode	LP, XT, HS	OST	OSTS	Not clocked or	]	
	HSPLL	OST + 2 ms	0313	Two-Speed Start-up (if		
	EC, RC, INTRC <sup>(1)</sup>	5-10 μs <b>(5)</b>		enabled) until primary clock source becomes		
	INTOSC <sup>(2)</sup>	1 ms <sup>(4)</sup>	IOFS	ready <sup>(3)</sup> .		

Note 1: In this instance, refers specifically to the INTRC clock source.

2: Includes both the INTOSC 8 MHz source and postscaler derived frequencies.

3: Two-Speed Start-up is covered in greater detail in Section 19.3 "Two-Speed Start-up".

4: Execution continues during the INTOSC stabilization period.

5: Required delay when waking from Sleep and all Idle modes. This delay runs concurrently with any other required delays (see Section 3.3 "Idle Modes").

#### 3.5.2 EXIT BY RESET

Normally, the device is held in Reset by the Oscillator Start-up Timer (OST) until the primary clock (defined in Configuration Register 1H) becomes ready. At that time, the OSTS bit is set and the device begins executing code.

Code execution can begin before the primary clock becomes ready. If either the Two-Speed Start-up (see Section 19.3 "Two-Speed Start-up") or Fail-Safe Clock Monitor (see Section 19.4 "Fail-Safe Clock Monitor") are enabled in Configuration Register 1H, the device may begin execution as soon as the Reset source has cleared. Execution is clocked by the INTOSC multiplexer driven by the internal oscillator block. Since the OSCCON register is cleared following all Resets, the INTRC clock source is selected. A higher speed clock may be selected by modifying the IRCF bits in the OSCCON register. Execution is clocked by the internal oscillator block until either the primary clock becomes ready, or a power managed mode is entered before the primary clock becomes ready; the primary clock is then shut down.

#### 3.5.3 EXIT BY WDT TIME-OUT

A WDT time-out will cause different actions, depending on which power managed mode the device is in when the time-out occurs.

If the device is not executing code (all Idle modes and Sleep mode), the time-out will result in a wake from the power managed mode (see Sections 3.2 through 3.4).

If the device is executing code (all Run modes), the time-out will result in a WDT Reset (see Section 19.2 "Watchdog Timer (WDT)").

The WDT timer and postscaler are cleared by executing a SLEEP or CLRWDT instruction, the loss of a currently selected clock source (if the Fail-Safe Clock Monitor is enabled) and modifying the IRCF bits in the OSCCON register if the internal oscillator block is the system clock source.

#### 3.5.4 EXIT WITHOUT AN OSCILLATOR START-UP DELAY

Certain exits from power managed modes do not invoke the OST at all. These are:

- PRI\_IDLE mode, where the primary clock source is not stopped; or
- the primary clock source is not any of LP, XT, HS or HSPLL modes.

In these cases, the primary clock source either does not require an oscillator start-up delay, since it is already running (PRI\_IDLE), or normally does not require an oscillator start-up delay (RC, EC and INTIO Oscillator modes).

However, a fixed delay (approximately  $10 \ \mu$ s) following the wake event is required when leaving Sleep and Idle modes. This delay is required for the CPU to prepare for execution. Instruction execution resumes on the first clock cycle following this delay.

#### 3.6 INTOSC Frequency Drift

The factory calibrates the internal oscillator block output (INTOSC) for 8 MHz (see Table 22-6). However, this frequency may drift as VDD or temperature changes, which can affect the controller operation in a variety of ways.

It is possible to adjust the INTOSC frequency by modifying the value in the OSCTUNE register (Register 2-1). This has the side effect that the INTRC clock source frequency is also affected. However, the features that use the INTRC source often do not require an exact frequency. These features include the Fail-Safe Clock Monitor, the Watchdog Timer and the RC\_RUN/ RC\_IDLE modes when the INTRC clock source is selected.

Being able to adjust the INTOSC requires knowing when an adjustment is required, in which direction it should be made and in some cases, how large a change is needed. Three examples follow but other techniques may be used.

#### 3.6.1 EXAMPLE – EUSART

An adjustment may be indicated when the EUSART begins to generate framing errors, or receives data with errors while in Asynchronous mode. Framing errors indicate that the system clock frequency is too high – try decrementing the value in the OSCTUNE register to reduce the system clock frequency. Errors in data may suggest that the system clock speed is too low – increment OSCTUNE.

#### 3.6.2 EXAMPLE – TIMERS

This technique compares system clock speed to some reference clock. Two timers may be used; one timer is clocked by the peripheral clock, while the other is clocked by a fixed reference source, such as the Timer1 oscillator.

Both timers are cleared, but the timer clocked by the reference generates interrupts. When an interrupt occurs, the internally clocked timer is read and both timers are cleared. If the internally clocked timer value is greater than expected, then the internal oscillator block is running too fast – decrement OSCTUNE.

## 3.6.3 EXAMPLE – CCP IN CAPTURE MODE

A CCP module can use free running Timer1 (or Timer3), clocked by the internal oscillator block and an external event with a known period (i.e., AC power frequency). The time of the first event is captured in the CCPRxH:CCPRxL registers and is recorded for use later. When the second event causes a capture, the time of the first event is subtracted from the time of the second event. Since the period of the external event is known, the time difference between events can be calculated.

If the measured time is much greater than the calculated time, the internal oscillator block is running too fast – decrement OSCTUNE. If the measured time is much less than the calculated time, the internal oscillator block is running too slow – increment OSCTUNE.

## PIC18F1220/1320

NOTES:

#### 4.0 RESET

The PIC18F1220/1320 devices differentiate between various kinds of Reset:

- a) Power-on Reset (POR)
- b) MCLR Reset during normal operation
- c) MCLR Reset during Sleep
- d) Watchdog Timer (WDT) Reset (during execution)
- e) Programmable Brown-out Reset (BOR)
- f) RESET Instruction
- g) Stack Full Reset
- h) Stack Underflow Reset

Most registers are unaffected by a Reset. Their status is unknown on POR and unchanged by all other Resets. The other registers are forced to a "Reset state", depending on the type of Reset that occurred. Most registers are not affected by a WDT wake-up, since this is viewed as the resumption of normal operation. Status bits from the RCON register (Register 4-1), RI, TO, PD, POR and BOR, are set or cleared differently in different Reset situations, as indicated in Table 4-2. These bits are used in software to determine the nature of the Reset. See Table 4-3 for a full description of the Reset states of all registers.

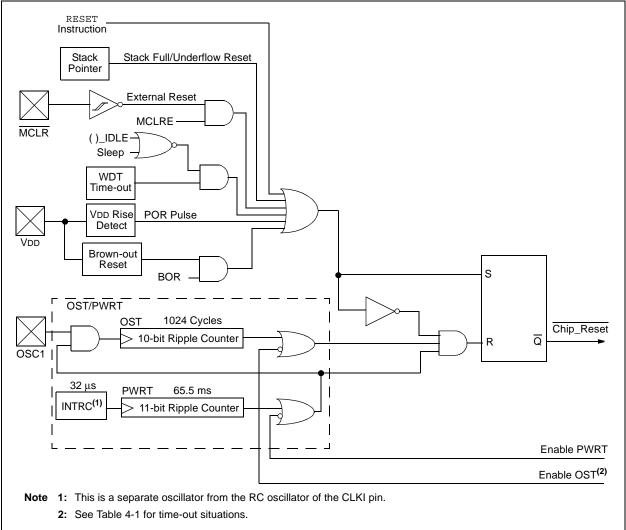

A simplified block diagram of the On-Chip Reset Circuit is shown in Figure 4-1.

The Enhanced MCU devices have a  $\overline{\text{MCLR}}$  noise filter in the  $\overline{\text{MCLR}}$  Reset path. The filter will detect and ignore small pulses.

The  $\overline{\text{MCLR}}$  pin is not driven low by any internal Resets, including the WDT.

The  $\overline{\text{MCLR}}$  input provided by the  $\overline{\text{MCLR}}$  pin can be disabled with the MCLRE bit in Configuration Register 3H (CONFIG3H<7>).

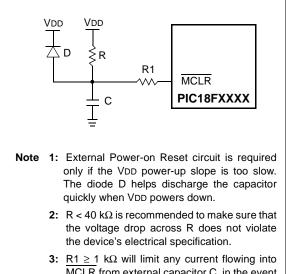

#### 4.1 Power-on Reset (POR)

A Power-on Reset pulse is generated on-chip when VDD rise is detected. To take advantage of the POR circuitry, just tie the MCLR pin through a resistor (1k to 10 k $\Omega$ ) to VDD. This will eliminate external RC components usually needed to create a Power-on Reset delay. A minimum rise rate for VDD is specified (parameter D004). For a slow rise time, see Figure 4-2.

When the device starts normal operation (i.e., exits the Reset condition), device operating parameters (voltage, frequency, temperature, etc.) must be met to ensure operation. If these conditions are not met, the device must be held in Reset until the operating conditions are met.

FIGURE 4-2: EXTERNAL POWER-ON RESET CIRCUIT (FOR SLOW VDD POWER-UP)

 <u>KT ≥ 1</u> K2 will mint any current howing into <u>MCLR</u> from external capacitor C, in the event of <u>MCLR/VPP</u> pin breakdown due to Electrostatic Discharge (ESD) or Electrical Overstress (EOS).

#### 4.2 **Power-up Timer (PWRT)**

The Power-up Timer (PWRT) of the PIC18F1220/1320 is an 11-bit counter, which uses the INTRC source as the clock input. This yields a count of  $2048 \times 32 \ \mu s = 65.6 \ ms$ . While the PWRT is counting, the device is held in Reset.

The power-up time delay will vary from chip-to-chip due to VDD, temperature and process variation. See DC parameter 33 for details.

The PWRT is enabled by clearing configuration bit, PWRTEN.

### 4.3 Oscillator Start-up Timer (OST)

The Oscillator Start-up Timer (OST) provides a 1024 oscillator cycle (from OSC1 input) delay after the PWRT delay is over (parameter 33). This ensures that the crystal oscillator or resonator has started and stabilized.

The OST time-out is invoked only for XT, LP, HS and HSPLL modes and only on Power-on Reset, or on exit from most low-power modes.

#### 4.4 PLL Lock Time-out

With the PLL enabled in its PLL mode, the time-out sequence following a Power-on Reset is slightly different from other oscillator modes. A portion of the Power-up Timer is used to provide a fixed time-out that is sufficient for the PLL to lock to the main oscillator frequency. This PLL lock time-out (TPLL) is typically 2 ms and follows the Oscillator Start-up Time-out.

#### 4.5 Brown-out Reset (BOR)

A configuration bit, BOR, can disable (if clear/ programmed), or enable (if set) the Brown-out Reset circuitry. If VDD falls below VBOR (parameter D005) for greater than TBOR (parameter 35), the brown-out situation will reset the chip. A Reset may not occur if VDD falls below VBOR for less than TBOR. The chip will remain in Brown-out Reset until VDD rises above VBOR. If the Power-up Timer is enabled, it will be invoked after VDD rises above VBOR; it then will keep the chip in Reset for an additional time delay, TPWRT (parameter 33). If VDD drops below VBOR while the Power-up Timer is running, the chip will go back into a Brown-out Reset and the Power-up Timer will be initialized. Once VDD rises above VBOR, the Power-up Timer will execute the additional time delay. Enabling BOR Reset does not automatically enable the PWRT.

#### 4.6 Time-out Sequence

On power-up, the time-out sequence is as follows: First, after the POR pulse has cleared, PWRT time-out is invoked (if enabled). Then, the OST is activated. The total time-out will vary based on oscillator configuration and the status of the PWRT. For example, in RC mode with the PWRT disabled, there will be no time-out at all. Figure 4-3, Figure 4-4, Figure 4-5, Figure 4-6 and Figure 4-7 depict time-out sequences on power-up.

Since the time-outs occur from the POR pulse, if  $\overline{\text{MCLR}}$  is kept low long enough, all time-outs will expire. Bringing  $\overline{\text{MCLR}}$  high will begin execution immediately (Figure 4-5). This is useful for testing purposes or to synchronize more than one PIC18FXXXX device operating in parallel.

Table 4-2 shows the Reset conditions for some Special Function Registers, while Table 4-3 shows the Reset conditions for all the registers.

#### TABLE 4-1: TIME-OUT IN VARIOUS SITUATIONS

Oscillator Configuration	Power-up <sup>(2)</sup> ar	Exit from	
	<b>PWRTEN =</b> 0	PWRTEN = 1	Low-Power Mode
HSPLL	66 ms <sup>(1)</sup> + 1024 Tosc + 2 ms <sup>(2)</sup>	1024 Tosc + 2 ms <sup>(2)</sup>	1024 Tosc + 2 ms <sup>(2)</sup>
HS, XT, LP	66 ms <sup>(1)</sup> + 1024 Tosc	1024 Tosc	1024 Tosc
EC, ECIO	66 ms <sup>(1)</sup>	5-10 μs <sup>(3)</sup>	5-10 μs <sup>(3)</sup>
RC, RCIO	66 ms <sup>(1)</sup>	5-10 μs <sup>(3)</sup>	5-10 μs <sup>(3)</sup>
INTIO1, INTIO2	66 ms <sup>(1)</sup>	5-10 μs <sup>(3)</sup>	5-10 μs <sup>(3)</sup>

Note 1: 66 ms (65.5 ms) is the nominal Power-up Timer (PWRT) delay.

2: 2 ms is the nominal time required for the 4x PLL to lock.

**3:** The program memory bias start-up time is always invoked on POR, wake-up from Sleep, or on any exit from power managed mode that disables the CPU and instruction execution.

# 5.0 MEMORY ORGANIZATION

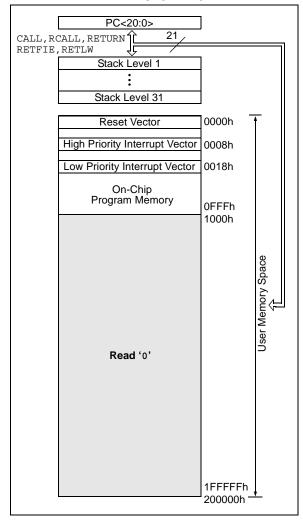

There are three memory types in Enhanced MCU devices. These memory types are:

- Program Memory
- Data RAM
- Data EEPROM

Data and program memory use separate busses, which allows for concurrent access of these types.

Additional detailed information for Flash program memory and data EEPROM is provided in Section 6.0 "Flash Program Memory" and Section 7.0 "Data EEPROM Memory", respectively.

#### FIGURE 5-1: PROGRAM MEMORY MAP AND STACK FOR PIC18F1220

# 5.1 Program Memory Organization

A 21-bit program counter is capable of addressing the 2-Mbyte program memory space. Accessing a location between the physically implemented memory and the 2-Mbyte address will cause a read of all '0's (a NOP instruction).

The PIC18F1220 has 4 Kbytes of Flash memory and can store up to 2,048 single-word instructions.

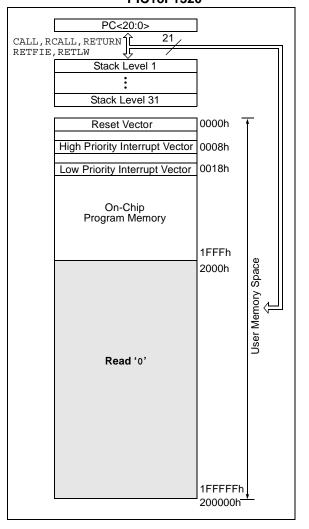

The PIC18F1320 has 8 Kbytes of Flash memory and can store up to 4,096 single-word instructions.

The Reset vector address is at 0000h and the interrupt vector addresses are at 0008h and 0018h.

The program memory maps for the PIC18F1220 and PIC18F1320 devices are shown in Figure 5-1 and Figure 5-2, respectively.

#### PROGRAM MEMORY MAP AND STACK FOR PIC18F1320

# 5.2 Return Address Stack

The return address stack allows any combination of up to 31 program calls and interrupts to occur. The PC (Program Counter) is pushed onto the stack when a CALL or RCALL instruction is executed, or an interrupt is Acknowledged. The PC value is pulled off the stack on a RETURN, RETLW or a RETFIE instruction. PCLATU and PCLATH are not affected by any of the RETURN or CALL instructions.

The stack operates as a 31-word by 21-bit RAM and a 5-bit stack pointer, with the Stack Pointer initialized to 00000B after all Resets. There is no RAM associated with Stack Pointer, 00000B. This is only a Reset value. During a CALL type instruction, causing a push onto the stack, the Stack Pointer is first incremented and the RAM location pointed to by the Stack Pointer (STKPTR) register is written with the contents of the PC (already pointing to the instruction, causing a pop from the stack, the contents of the RAM location pointed to by the STKPTR). During a RETURN type instruction, causing a pop from the stack, the contents of the RAM location pointed to by the STKPTR are transferred to the PC and then the Stack Pointer is decremented.

The stack space is not part of either program or data space. The Stack Pointer is readable and writable and the address on the top of the stack is readable and writable through the top-of-stack Special File Registers. Data can also be pushed to or popped from the stack using the top-of-stack SFRs. Status bits indicate if the stack is full, has overflowed or underflowed.

### 5.2.1 TOP-OF-STACK ACCESS

The top of the stack is readable and writable. Three register locations, TOSU, TOSH and TOSL, hold the contents of the stack location pointed to by the STKPTR register (Figure 5-3). This allows users to implement a software stack if necessary. After a CALL, RCALL or interrupt, the software can read the pushed value by reading the TOSU, TOSH and TOSL registers. These values can be placed on a user defined software stack. At return time, the software can replace the TOSU, TOSH and TOSL and do a return.

The user must disable the global interrupt enable bits while accessing the stack to prevent inadvertent stack corruption.

### 5.2.2 RETURN STACK POINTER (STKPTR)

The STKPTR register (Register 5-1) contains the stack pointer value, the STKFUL (Stack Full) status bit and the STKUNF (Stack Underflow) status bits. The value of the Stack Pointer can be 0 through 31. The Stack Pointer increments before values are pushed onto the stack and decrements after values are popped off the stack. At Reset, the Stack Pointer value will be zero. The user may read and write the Stack Pointer value. This feature can be used by a Real-Time Operating System for return stack maintenance.

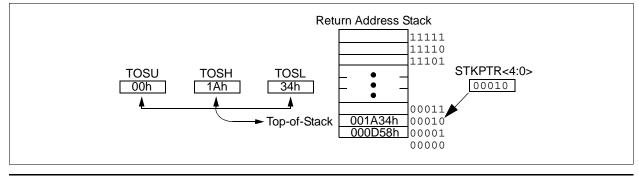

After the PC is pushed onto the stack 31 times (without popping any values off the stack), the STKFUL bit is set. The STKFUL bit is cleared by software or by a POR.

The action that takes place when the stack becomes full depends on the state of the STVR (Stack Overflow Reset Enable) configuration bit. (Refer to **Section 19.1** "**Configuration Bits**" for a description of the device configuration bits.) If STVR is set (default), the 31st push will push the (PC + 2) value onto the stack, set the STKFUL bit and reset the device. The STKFUL bit will remain set and the Stack Pointer will be set to zero.

If STVR is cleared, the STKFUL bit will be set on the 31st push and the Stack Pointer will increment to 31. Any additional pushes will not overwrite the 31st push and STKPTR will remain at 31.

When the stack has been popped enough times to unload the stack, the next pop will return a value of zero to the PC and sets the STKUNF bit, while the Stack Pointer remains at zero. The STKUNF bit will remain set until cleared by software or a POR occurs.

#### FIGURE 5-3: RETURN ADDRESS STACK AND ASSOCIATED REGISTERS

**Note:** Returning a value of zero to the PC on an underflow has the effect of vectoring the program to the Reset vector, where the stack conditions can be verified and appropriate actions can be taken. This is not the same as a Reset, as the contents of the SFRs are not affected.

**REGISTER 5-1: STKPTR REGISTER**

### 5.2.3 PUSH AND POP INSTRUCTIONS

Since the Top-of-Stack (TOS) is readable and writable, the ability to push values onto the stack and pull values off the stack, without disturbing normal program execution, is a desirable option. To push the current PC value onto the stack, a PUSH instruction can be executed. This will increment the Stack Pointer and load the current PC value onto the stack. TOSU, TOSH and TOSL can then be modified to place data or a return address on the stack.

The ability to pull the TOS value off of the stack and replace it with the value that was previously pushed onto the stack, without disturbing normal execution, is achieved by using the POP instruction. The POP instruction discards the current TOS by decrementing the Stack Pointer. The previous value pushed onto the stack then becomes the TOS value.

### 5.2.4 STACK FULL/UNDERFLOW RESETS

These Resets are enabled by programming the STVR bit in Configuration Register 4L. When the STVR bit is cleared, a full or underflow condition will set the appropriate STKFUL or STKUNF bit, but not cause a device Reset. When the STVR bit is set, a full or underflow condition will set the appropriate STKFUL or STKUNF bit and then cause a device Reset. The STKFUL or STKUNF bits are cleared by the user software or a Power-on Reset.

# 5.3 Fast Register Stack

A "fast return" option is available for interrupts. A fast register stack is provided for the Status, WREG and BSR registers and is only one in depth. The stack is not readable or writable and is loaded with the current value of the corresponding register when the processor vectors for an interrupt. The values in the registers are then loaded back into the working registers, if the RETFIE, FAST instruction is used to return from the interrupt.

All interrupt sources will push values into the stack registers. If both low and high priority interrupts are enabled, the stack registers cannot be used reliably to return from low priority interrupts. If a high priority interrupt occurs while servicing a low priority interrupt, the stack register values stored by the low priority interrupt will be overwritten. Users must save the key registers in software during a low priority interrupt.

If interrupt priority is not used, all interrupts may use the fast register stack for returns from interrupt.

If no interrupts are used, the fast register stack can be used to restore the Status, WREG and BSR registers at the end of a subroutine call. To use the fast register stack for a subroutine call, a CALL LABEL, FAST instruction must be executed to save the Status, WREG and BSR registers to the fast register stack. A RETURN, FAST instruction is then executed to restore these registers from the fast register stack.

Example 5-1 shows a source code example that uses the fast register stack during a subroutine call and return.

#### EXAMPLE 5-1: FAST REGISTER STACK CODE EXAMPLE

CALL SUB1, FAST	;STATUS, WREG, BSR ;SAVED IN FAST REGISTER ;STACK
sub1	
• RETURN, FAST	;RESTORE VALUES SAVED ;IN FAST REGISTER STACK

# 5.4 PCL, PCLATH and PCLATU

The Program Counter (PC) specifies the address of the instruction to fetch for execution. The PC is 21-bits wide. The low byte, known as the PCL register, is both readable and writable. The high byte, or PCH register, contains the PC<15:8> bits and is not directly readable or writable. Updates to the PCH register may be performed through the PCLATH register. The upper byte is called PCU. This register contains the PC<20:16> bits and is not directly readable or writable. Updates to the PCLATH register. Updates to the PCU register may be performed through the PCLATH register. Updates to the PCU register may be performed through the PCLATU register.

The contents of PCLATH and PCLATU will be transferred to the program counter by any operation that writes PCL. Similarly, the upper two bytes of the program counter will be transferred to PCLATH and PCLATU by an operation that reads PCL. This is useful for computed offsets to the PC (see **Section 5.8.1** "**Computed GOTO**").

The PC addresses bytes in the program memory. To prevent the PC from becoming misaligned with word instructions, the LSB of PCL is fixed to a value of '0'. The PC increments by 2 to address sequential instructions in the program memory.

The CALL, RCALL, GOTO and program branch instructions write to the program counter directly. For these instructions, the contents of PCLATH and PCLATU are not transferred to the program counter.

### 5.5 Clocking Scheme/Instruction Cycle

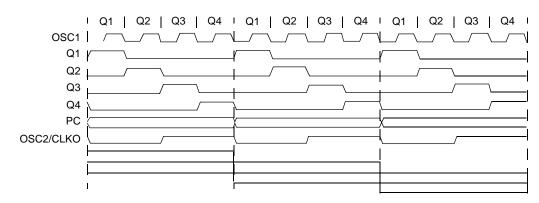

The clock input (from OSC1) is internally divided by four to generate four non-overlapping quadrature clocks, namely Q1, Q2, Q3 and Q4. Internally, the Program Counter (PC) is incremented every Q1, the instruction is fetched from the program memory and latched into the instruction register in Q4. The instruction is decoded and executed during the following Q1 through Q4. The clocks and instruction execution flow are shown in Figure 5-4.

# 5.6 Instruction Flow/Pipelining

An "Instruction Cycle" consists of four Q cycles (Q1, Q2, Q3 and Q4). The instruction fetch and execute are pipelined such that fetch takes one instruction cycle, while decode and execute takes another instruction cycle. However, due to the pipelining, each instruction effectively executes in one cycle. If an instruction causes the program counter to change (e.g., GOTO), then two cycles are required to complete the instruction (Example 5-2).

A fetch cycle begins with the Program Counter (PC) incrementing in Q1.

In the execution cycle, the fetched instruction is latched into the "Instruction Register" (IR) in cycle Q1. This instruction is then decoded and executed during the Q2, Q3 and Q4 cycles. Data memory is read during Q2 (operand read) and written during Q4 (destination write).

### FIGURE 5-4: CLOCK/INSTRUCTION CYCLE

### EXAMPLE 5-2: INSTRUCTION PIPELINE FLOW

## 5.7 Instructions in Program Memory

The program memory is addressed in bytes. Instructions are stored as two bytes or four bytes in program memory. The Least Significant Byte of an instruction word is always stored in a program memory location with an even address (LSB = 0). Figure 5-5 shows an example of how instruction words are stored in the program memory. To maintain alignment with instruction boundaries, the PC increments in steps of 2 and the LSB will always read '0' (see Section 5.4 "PCL, PCLATH and PCLATU"). The CALL and GOTO instructions have the absolute program memory address embedded into the instruction. Since instructions are always stored on word boundaries, the data contained in the instruction is a word address. The word address is written to PC<20:1>, which accesses the desired byte address in program memory. Instruction #2 in Figure 5-5 shows how the instruction 'GOTO 00006h' is encoded in the program memory. Program branch instructions, which encode a relative address offset, operate in the same manner. The offset value stored in a branch instruction represents the number of single-word instructions that the PC will be offset by. **Section 20.0 "Instruction Set Summary"** provides further details of the instruction set.

			<b>LSB</b> = 1	LSB = 0	Word Address $\downarrow$
	Program N				000000h
	Byte Locat	ions $\rightarrow$			000002h
		-			000004h

		-			000012h
		ľ			000014h

#### FIGURE 5-5: INSTRUCTIONS IN PROGRAM MEMORY

### 5.7.1 TWO-WORD INSTRUCTIONS

PIC18F1220/1320 devices have four two-word instructions: MOVFF, CALL, GOTO and LFSR. The second word of these instructions has the 4 MSBs set to '1's and is decoded as a NOP instruction. The lower 12 bits of the second word contain data to be used by the instruction. If the first word of the instruction is executed, the data in the second word is accessed. If the second word of the

instruction is executed by itself (first word was skipped), it will execute as a NOP. This action is necessary when the two-word instruction is preceded by a conditional instruction that results in a skip operation. A program example that demonstrates this concept is shown in Example 5-3. Refer to **Section 20.0 "Instruction Set Summary"** for further details of the instruction set.

### EXAMPLE 5-3: TWO-WORD INSTRUCTIONS

CASE 1:						
Object Code	Source Code					
0110 0110 0000 0000	TSTFSZ REG1	; is RAM location 0?				
1100 0001 0010 0011	MOVFF REG1, REG2	; No, skip this word				
1111 0100 0101 0110		; Execute this word as a NOP				
0010 0100 0000 0000	ADDWF REG3	; continue code				
CASE 2:						
Object Code	Source Code					
0110 0110 0000 0000	TSTFSZ REG1	; is RAM location 0?				
1100 0001 0010 0011	MOVFF REG1, REG2	; Yes, execute this word				
1111 0100 0101 0110		; 2nd word of instruction				
0010 0100 0000 0000	ADDWF REG3	; continue code				

## 5.8 Look-up Tables

Look-up tables are implemented two ways:

- Computed GOTO
- Table Reads

## 5.8.1 COMPUTED GOTO

A computed GOTO is accomplished by adding an offset to the program counter (see Example 5-4).

A look-up table can be formed with an ADDWF PCL instruction and a group of RETLW 0xnn instructions. WREG is loaded with an offset into the table before executing a call to that table. The first instruction of the called routine is the ADDWF PCL instruction. The next instruction executed will be one of the RETLW 0xnn instructions, that returns the value 0xnn to the calling function.

The offset value (in WREG) specifies the number of bytes that the program counter should advance and should be multiples of 2 (LSB = 0).

In this method, only one data byte may be stored in each instruction location and room on the return address stack is required.

#### EXAMPLE 5-4: COMPUTED GOTO USING AN OFFSET VALUE

	MOVFW CALL	OFFSET TABLE
ORG	0xnn00	
TABLE	ADDWF	PCL
	RETLW	0xnn
	RETLW	0xnn
	RETLW	0xnn
	•	
	•	

### 5.8.2 TABLE READS/TABLE WRITES

A better method of storing data in program memory allows two bytes of data to be stored in each instruction location.

Look-up table data may be stored two bytes per program word by using table reads and writes. The Table Pointer (TBLPTR) register specifies the byte address and the Table Latch (TABLAT) register contains the data that is read from or written to program memory. Data is transferred to/from program memory, one byte at a time.

The table read/table write operation is discussed further in Section 6.1 "Table Reads and Table Writes".

# 5.9 Data Memory Organization

The data memory is implemented as static RAM. Each register in the data memory has a 12-bit address, allowing up to 4096 bytes of data memory. Figure 5-6 shows the data memory organization for the PIC18F1220/1320 devices.

The data memory map is divided into as many as 16 banks that contain 256 bytes each. The lower 4 bits of the Bank Select Register (BSR<3:0>) select which bank will be accessed. The upper 4 bits for the BSR are not implemented.

The data memory contains Special Function Registers (SFR) and General Purpose Registers (GPR). The SFRs are used for control and status of the controller and peripheral functions, while GPRs are used for data storage and scratch pad operations in the user's application. The SFRs start at the last location of Bank 15 (FFFh) and extend towards F80h. Any remaining space beyond the SFRs in the Bank may be implemented as GPRs. GPRs start at the first location of Bank 0 and grow upwards. Any read of an unimplemented location will read as '0's.

The entire data memory may be accessed directly or indirectly. Direct addressing may require the use of the BSR register. Indirect addressing requires the use of a File Select Register (FSRn) and a corresponding Indirect File Operand (INDFn). Each FSR holds a 12-bit address value that can be used to access any location in the Data Memory map without banking. See Section 5.12 "Indirect Addressing, INDF and FSR Registers" for indirect addressing details.

The instruction set and architecture allow operations across all banks. This may be accomplished by indirect addressing or by the use of the MOVFF instruction. The MOVFF instruction is a two-word/two-cycle instruction that moves a value from one register to another.

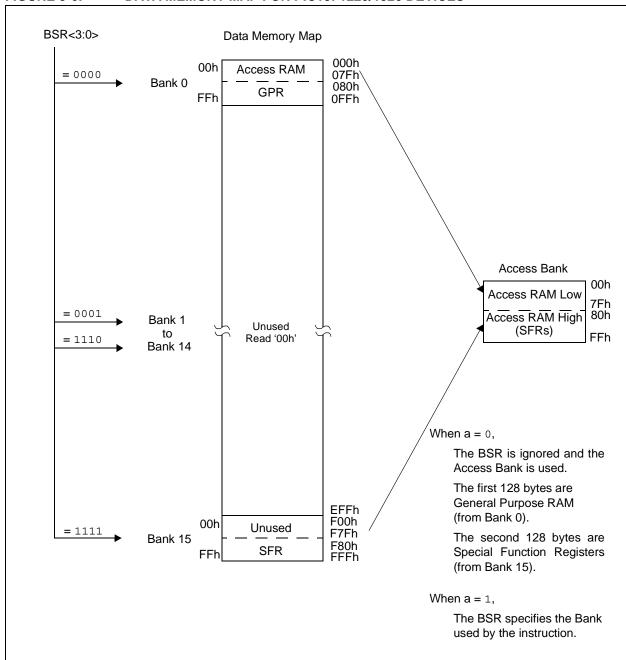

To ensure that commonly used registers (SFRs and select GPRs) can be accessed in a single cycle, regardless of the current BSR values, an Access Bank is implemented. A segment of Bank 0 and a segment of Bank 15 comprise the Access RAM. **Section 5.10 "Access Bank"** provides a detailed description of the Access RAM.

#### 5.9.1 GENERAL PURPOSE REGISTER FILE

Enhanced MCU devices may have banked memory in the GPR area. GPRs are not initialized by a Power-on Reset and are unchanged on all other Resets.

Data RAM is available for use as GPR registers by all instructions. The second half of Bank 15 (F80h to FFFh) contains SFRs. All other banks of data memory contain GPRs, starting with Bank 0.

# PIC18F1220/1320

#### FIGURE 5-6: DATA MEMORY MAP FOR PIC18F1220/1320 DEVICES

#### 5.9.2 SPECIAL FUNCTION REGISTERS

The Special Function Registers (SFRs) are registers used by the CPU and peripheral modules for controlling the desired operation of the device. These registers are implemented as static RAM. A list of these registers is given in Table 5-1 and Table 5-2. The SFRs can be classified into two sets: those associated with the "core" function and those related to the peripheral functions. Those registers related to the "core" are described in this section, while those related to the operation of the peripheral features are described in the section of that peripheral feature.

The SFRs are typically distributed among the peripherals whose functions they control.

The unused SFR locations will be unimplemented and read as '0's.

TABLE 5-2:	<b>REGISTER FILE SUMMARY</b>	(PIC18F1220/1320)	(CONTINUED)

**Legend:** x = unknown, u = unchanged, - = unimplemented, q = value depends on condition **Note 1:** RA6 and associated bits are configured as port pins in RCIO, ECIO and INTIO2 (with port function on RA6) Oscillator mode only and read '0' in all other oscillator modes.

RA7 and associated bits are configured as port pins in INTIO2 Oscillator mode only and read '0' in all other modes. 2:

Bit 21 of the PC is only available in Test mode and Serial Programming modes.
 The RA5 port bit is only available when MCLRE fuse (CONFIG3H<7>) is programmed to '0'. Otherwise, RA5 reads '0'. This bit is read-only.

# 5.10 Access Bank

The Access Bank is an architectural enhancement which is very useful for C compiler code optimization. The techniques used by the C compiler may also be useful for programs written in assembly.

This data memory region can be used for:

- · Intermediate computational values
- · Local variables of subroutines
- · Faster context saving/switching of variables
- Common variables
- Faster evaluation/control of SFRs (no banking)

The Access Bank is comprised of the last 128 bytes in Bank 15 (SFRs) and the first 128 bytes in Bank 0. These two sections will be referred to as Access RAM High and Access RAM Low, respectively. Figure 5-6 indicates the Access RAM areas.

A bit in the instruction word specifies if the operation is to occur in the bank specified by the BSR register or in the Access Bank. This bit is denoted as the 'a' bit (for access bit).

When forced in the Access Bank (a = 0), the last address in Access RAM Low is followed by the first address in Access RAM High. Access RAM High maps the Special Function Registers, so these registers can be accessed without any software overhead. This is useful for testing status flags and modifying control bits.

# 5.11 Bank Select Register (BSR)

The need for a large general purpose memory space dictates a RAM banking scheme. The data memory is partitioned into as many as sixteen banks. When using direct addressing, the BSR should be configured for the desired bank.

BSR<3:0> holds the upper 4 bits of the 12-bit RAM address. The BSR<7:4> bits will always read '0's and writes will have no effect (see Figure 5-7).

A MOVLB instruction has been provided in the instruction set to assist in selecting banks.

If the currently selected bank is not implemented, any read will return all '0's and all writes are ignored. The Status register bits will be set/cleared as appropriate for the instruction performed.

Each Bank<sub>0</sub>extends up to FFh (256 bytes). All data memory is implemented as static RAM.

A MOVFF instruction ignores the BSR, since the 12-bit addresses are embedded into the instruction word.

Section 5.12 "Indirect Addressing, INDF and FSR Registers" provides a desctruc6oru3, INDFtIN1.21 12.2(58S(IN F)1c.5(5(

# 5.12 Indirect Addressing, INDF and FSR Registers

Indirect addressing is a mode of addressing data memory, where the data memory address in the instruction is not fixed. An FSR register is used as a pointer to the data memory location that is to be read or written. Since this pointer is in RAM, the contents can be modified by the program. This can be useful for data tables in the data memory and for software stacks. Figure 5-8 shows how the fetched instruction is modified prior to being executed.

Indirect addressing is possible by using one of the INDF registers. Any instruction, using the INDF register, actually accesses the register pointed to by the File Select Register, FSR. Reading the INDF register itself, indirectly (FSR = 0), will read 00h. Writing to the INDF register indirectly, results in a no operation (NOP). The FSR register contains a 12-bit address, which is shown in Figure 5-9.

The INDFn register is not a physical register. Addressing INDFn actually addresses the register whose address is contained in the FSRn register (FSRn is a pointer). This is indirect addressing.

Example 5-5 shows a simple use of indirect addressing to clear the RAM in Bank 1 (locations 100h-1FFh) in a minimum number of instructions.

#### EXAMPLE 5-5: HOW TO CLEAR RAM (BANK 1) USING INDIRECT ADDRESSING

	LFSR	FSR0,0x100	;
NEXT	CLRF	POSTINC0	; Clear INDF
			; register then
			; inc pointer
	BTFSS	FSROH, 1	; All done with
			; Bank1?
	GOTO	NEXT	; NO, clear next
CONTINU	JE		; YES, continue

There are three indirect addressing registers. To address the entire data memory space (4096 bytes), these registers are 12-bit wide. To store the 12 bits of addressing information, two 8-bit registers are required:

- 1. FSR0: composed of FSR0H:FSR0L
- 2. FSR1: composed of FSR1H:FSR1L
- 3. FSR2: composed of FSR2H:FSR2L

In addition, there are registers INDF0, INDF1 and INDF2, which are not physically implemented. Reading or writing to these registers activates indirect addressing, with the value in the corresponding FSR register being the address of the data. If an instruction writes a value to INDF0, the value will be written to the address pointed to by FSR0H:FSR0L. A read from INDF1 reads the data from the address pointed to by FSR1H:FSR1L. INDFn can be used in code anywhere an operand can be used.

If INDF0, INDF1 or INDF2 are read indirectly via an FSR, all '0's are read (zero bit is set). Similarly, if INDF0, INDF1 or INDF2 are written to indirectly, the operation will be equivalent to a NOP instruction and the Status bits are not affected.

### 5.12.1 INDIRECT ADDRESSING OPERATION

Each FSR register has an INDF register associated with it, plus four additional register addresses. Performing an operation using one of these five registers determines how the FSR will be modified during indirect addressing.

When data access is performed using one of the five INDFn locations, the address selected will configure the FSRn register to:

- Do nothing to FSRn after an indirect access (no change) INDFn
- Auto-decrement FSRn after an indirect access (post-decrement) POSTDECn
- Auto-increment FSRn after an indirect access (post-increment) POSTINCn
- Auto-increment FSRn before an indirect access (pre-increment) PREINCn
- Use the value in the WREG register as an offset to FSRn. Do not modify the value of the WREG or the FSRn register after an indirect access (no change) – PLUSWn

When using the auto-increment or auto-decrement features, the effect on the FSR is not reflected in the Status register. For example, if the indirect address causes the FSR to equal '0', the Z bit will not be set.

Auto-incrementing or auto-decrementing an FSR affects all 12 bits. That is, when FSRnL overflows from an increment, FSRnH will be incremented automatically.

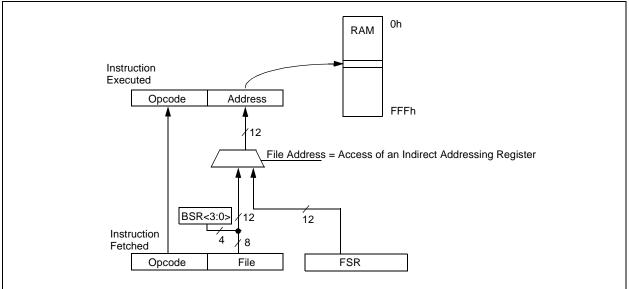

Adding these features allows the FSRn to be used as a stack pointer, in addition to its uses for table operations in data memory.

Each FSR has an address associated with it that performs an indexed indirect access. When a data access to this INDFn location (PLUSWn) occurs, the FSRn is configured to add the signed value in the WREG register and the value in FSR to form the address before an indirect access. The FSR value is not changed. The WREG offset range is -128 to +127.

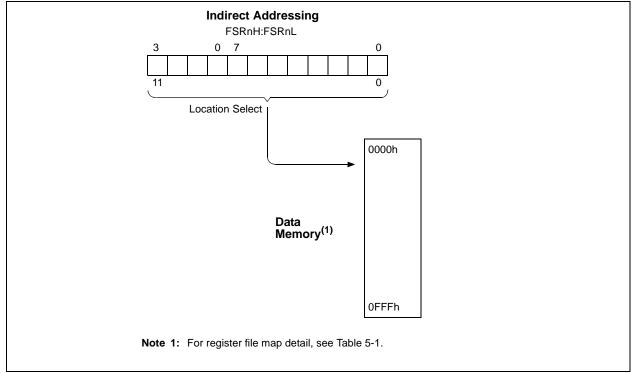

If an FSR register contains a value that points to one of the INDFn, an indirect read will read 00h (zero bit is set), while an indirect write will be equivalent to a NOP (Status bits are not affected).

If an indirect addressing write is performed when the target address is an FSRnH or FSRnL register, the data is written to the FSR register, but no pre- or post-increment/ decrement is performed.

### FIGURE 5-9: INDIRECT ADDRESSING

# 5.13 Status Register

The Status register, shown in Register 5-2, contains the arithmetic status of the ALU. As with any other SFR, it can be the operand for any instruction.

If the Status register is the destination for an instruction that affects the Z, DC, C, OV or N bits, the results of the instruction are not written; instead, the status is updated according to the instruction performed. Therefore, the result of an instruction with the Status register as its destination may be different than intended. As an example, CLRF STATUS will set the Z bit and leave the remaining Status bits unchanged ('000u uluu'). It is recommended that only BCF, BSF, SWAPF, MOVFF and MOVWF instructions are used to alter the Status register, because these instructions do not affect the Z, C, DC, OV or N bits in the Status register.

For other instructions that do not affect Status bits, see the instruction set summaries in Table 20-1.

Note: The C and DC bits operate as the borrow and digit borrow bits, respectively, in subtraction.

## REGISTER 5-2: STATUS REGISTER

U-0	U-0	U-0	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x
	—	—	N	OV	Z	DC	С

	<b>Note:</b> For borrow, the polarity is reversed. A subtraction is executed by adding the 2's complement of the second operand. For rotate (RRF, RLF) instructions, this bit is loaded with either the high or low-order bit of the source register.							
	Legend:							
	R = Reada	ble bit	W = Writable bit	U = Unimplemented	bit, read as '0'			
	-n = Value	at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown			

## 5.14 RCON Register

The Reset Control (RCON) register contains flag bits that allow differentiation between the sources of a device Reset. These flags include the TO, PD, POR, BOR and RI bits. This register is readable and writable.

- Note 1: If the BOR configuration bit is set (Brownout Reset enabled), the BOR bit is '1' on a Power-on Reset. After a Brown-out Reset has occurred, the BOR bit will be cleared and must be set by firmware to indicate the occurrence of the next Brown-out Reset.
  - 2: It is recommended that the POR bit be set after a Power-on Reset has been detected, so that subsequent Power-on Resets may be detected.

#### REGISTER 5-3: RCON REGISTER

R/W-0	U-0	U-0	R/W-1	R-1	R-1	R/W-0	R/W-0
IPEN	—	_	RI	TO	PD	POR	BOR

- 0 = Disable priority levels on interrupts (PIC16CXXX Compatibility mode)

#### bit 6-5 Unimplemented: Read as '0'

- bit 4 RI: RESET Instruction Flag bit
  - 1 = The RESET instruction was not executed (set by firmware only)
  - 0 = The RESET instruction was executed causing a device Reset (must be set in software after a Brown-out Reset occurs)
- bit 3 **TO:** Watchdog Time-out Flag bit
  - 1 = Set by power-up, CLRWDT instruction or SLEEP instruction
  - 0 = A WDT time-out occurred
- bit 2 PD: Power-down Detection Flag bit
  - 1 = Set by power-up or by the CLRWDT instruction
  - 0 = Cleared by execution of the SLEEP instruction
- bit 1 POR: Power-on Reset Status bit
  - 1 = A Power-on Reset has not occurred (set by firmware only)
  - 0 = A Power-on Reset occurred (must be set in software after a Power-on Reset occurs)
- bit 0 BOR: Brown-out Reset Status bit
  - 1 = A Brown-out Reset has not occurred (set by firmware only)
  - 0 = A Brown-out Reset occurred (must be set in software after a Brown-out Reset occurs)

Legend:			
R = Readable bit	W = Writable bit	U = Unimplemented	l bit, read as '0'
-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

# 6.0 FLASH PROGRAM MEMORY

The Flash program memory is readable, writable and erasable during normal operation over the entire VDD range.

A read from program memory is executed on one byte at a time. A write to program memory is executed on blocks of 8 bytes at a time. Program memory is erased in blocks of 64 bytes at a time. A "Bulk Erase" operation may not be issued from user code.

While writing or erasing program memory, instruction fetches cease until the operation is complete. The program memory cannot be accessed during the write or erase, therefore, code cannot execute. An internal programming timer terminates program memory writes and erases.

A value written to program memory does not need to be a valid instruction. Executing a program memory location that forms an invalid instruction results in a NOP.

## 6.1 Table Reads and Table Writes

In order to read and write program memory, there are two operations that allow the processor to move bytes between the program memory space and the data RAM:

- Table Read (TBLRD)
- Table Write (TBLWT)

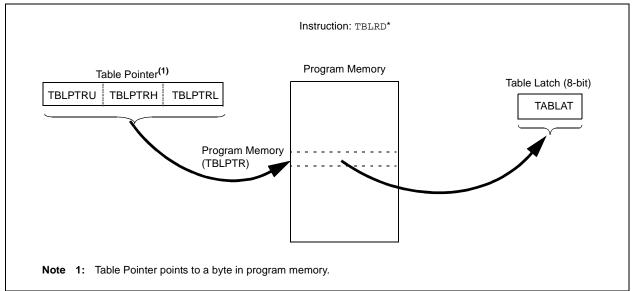

The program memory space is 16 bits wide, while the data RAM space is 8 bits wide. Table reads and table writes move data between these two memory spaces through an 8-bit register (TABLAT).

Table read operations retrieve data from program memory and place it into TABLAT in the data RAM space. Figure 6-1 shows the operation of a table read with program memory and data RAM.

Table write operations store data from TABLAT in the data memory space into holding registers in program memory. The procedure to write the contents of the holding registers into program memory is detailed in **Section 6.5 "Writing to Flash Program Memory"**. Figure 6-2 shows the operation of a table write with program memory and data RAM.

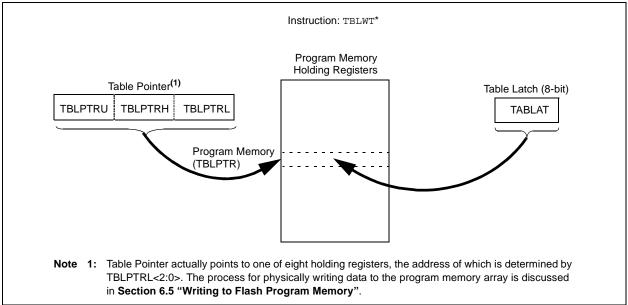

Table operations work with byte entities. A table block containing data, rather than program instructions, is not required to be word aligned. Therefore, a table block can start and end at any byte address. If a table write is being used to write executable code into program memory, program instructions will need to be word aligned (TBLPTRL<0> = 0).

The EEPROM on-chip timer controls the write and erase times. The write and erase voltages are generated by an on-chip charge pump rated to operate over the voltage range of the device for byte or word operations.

#### FIGURE 6-1: TABLE READ OPERATION

# 6.2 Control Registers

Several control registers are used in conjunction with the TBLRD and TBLWT instructions. These include the:

- EECON1 register
- EECON2 register
- TABLAT register
- TBLPTR registers

### 6.2.1 EECON1 AND EECON2 REGISTERS

EECON1 is the control register for memory accesses.

EECON2 is not a physical register. Reading EECON2 will read all '0's. The EECON2 register is used exclusively in the memory write and erase sequences.

Control bit, EEPGD, determines if the access will be to program or data EEPROM memory. When clear, operations will access the data EEPROM memory. When set, program memory is accessed.

Control bit, CFGS, determines if the access will be to the configuration registers, or to program memory/data EEPROM memory. When set, subsequent operations access configuration registers. When CFGS is clear, the EEPGD bit selects either program Flash or data EEPROM memory.

The FREE bit controls program memory erase operations. When the FREE bit is set, the erase operation is initiated on the next WR command. When FREE is clear, only writes are enabled. The WREN bit enables and disables erase and write operations. When set, erase and write operations are allowed. When clear, erase and write operations are disabled – the WR bit cannot be set while the WREN bit is clear. This process helps to prevent accidental writes to memory due to errant (unexpected) code execution.

Firmware should keep the WREN bit clear at all times, except when starting erase or write operations. Once firmware has set the WR bit, the WREN bit may be cleared. Clearing the WREN bit will not affect the operation in progress.

The WRERR bit is set when a write operation is interrupted by a Reset. In these situations, the user can check the WRERR bit and rewrite the location. It will be necessary to reload the data and address registers (EEDATA and EEADR) as these registers have cleared as a result of the Reset.

Control bits, RD and WR, start read and erase/write operations, respectively. These bits are set by firmware and cleared by hardware at the completion of the operation.

The RD bit cannot be set when accessing program memory (EEPGD = 1). Program memory is read using table read instructions. See **Section 6.3** "**Reading the Flash Program Memory**" regarding table reads.

**Note:** Interrupt flag bit, EEIF in the PIR2 register, is set when the write is complete. It must be cleared in software.

#### 6.2.2 TABLAT – TABLE LATCH REGISTER

The Table Latch (TABLAT) is an 8-bit register mapped into the SFR space. The table latch is used to hold 8-bit data during data transfers between program memory and data RAM.

#### 6.2.3 TBLPTR – TABLE POINTER REGISTER

The Table Pointer (TBLPTR) addresses a byte within the program memory. The TBLPTR is comprised of three SFR registers: Table Pointer Upper Byte, Table Pointer High Byte and Table Pointer Low Byte (TBLPTRU:TBLPTRH:TBLPTRL). These three registers join to form a 22-bit wide pointer. The low-order 21 bits allow the device to address up to 2 Mbytes of program memory space. Setting the 22nd bit allows access to the device ID, the user ID and the configuration bits.

The Table Pointer (TBLPTR) register is used by the TBLRD and TBLWT instructions. These instructions can update the TBLPTR in one of four ways based on the table operation. These operations are shown in Table 6-1. These operations on the TBLPTR only affect the low-order 21 bits.

#### 6.2.4 TABLE POINTER BOUNDARIES

TBLPTR is used in reads, writes and erases of the Flash program memory.

When a TBLRD is executed, all 22 bits of the Table Pointer determine which byte is read from program or configuration memory into TABLAT.

When a TBLWT is executed, the three LSbs of the Table Pointer (TBLPTR<2:0>) determine which of the eight program memory holding registers is written to. When the timed write to program memory (long write) begins, the 19 MSbs of the Table Pointer (TBLPTR<21:3>) will determine which program memory block of 8 bytes is written to (TBLPTR<2:0> are ignored). For more detail, see **Section 6.5 "Writing to Flash Program Memory"**.

When an erase of program memory is executed, the 16 MSbs of the Table Pointer (TBLPTR<21:6>) point to the 64-byte block that will be erased. The Least Significant bits (TBLPTR<5:0>) are ignored.

Figure 6-3 describes the relevant boundaries of TBLPTR based on Flash program memory operations.

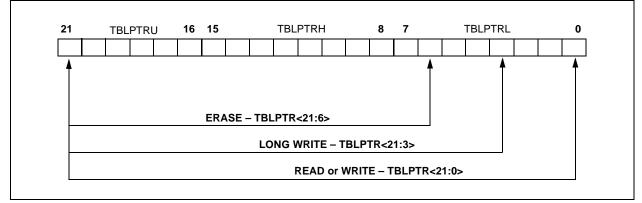

TABLE 6-1:	TABLE POINTER OPERATIONS WITH TBERD AND TBEWT INSTRUCTIONS

## 6.3 Reading the Flash Program Memory

The TBLRD instruction is used to retrieve data from program memory and place it into data RAM. Table reads from program memory are performed one byte at a time.

TBLPTR points to a byte address in program space. Executing a TBLRD instruction places the byte pointed to into TABLAT. In addition, TBLPTR can be modified automatically for the next table read operation. The internal program memory is typically organized by words. The Least Significant bit of the address selects between the high and low bytes of the word. Figure 6-4 shows the interface between the internal program memory and the TABLAT.

# FIGURE 6-4: READS FROM FLASH PROGRAM MEMORY

	MOVWF	WORD_ODD		

# 6.4 Erasing Flash Program Memory

The minimum erase block size is 32 words or 64 bytes under firmware control. Only through the use of an external programmer, or through ICSP control, can larger blocks of program memory be bulk erased. Word erase in Flash memory is not supported.

When initiating an erase sequence from the microcontroller itself, a block of 64 bytes of program memory is erased. The Most Significant 16 bits of the TBLPTR<21:6> point to the block being erased. TBLPTR<5:0> are ignored.

The EECON1 register commands the erase operation. The EEPGD bit must be set to point to the Flash program memory. The CFGS bit must be clear to access program Flash and data EEPROM memory. The WREN bit must be set to enable write operations. The FREE bit is set to select an erase operation. The WR bit is set as part of the required instruction sequence (as shown in Example 6-2) and starts the actual erase operation. It is not necessary to load the TABLAT register with any data as it is ignored.

For protection, the write initiate sequence using EECON2 must be used.

A long write is necessary for erasing the internal Flash. Instruction execution is halted while in a long write cycle. The long write will be terminated by the internal programming timer.

#### 6.4.1 FLASH PROGRAM MEMORY ERASE SEQUENCE

The sequence of events for erasing a block of internal program memory location is:

- 1. Load Table Pointer with address of row being erased.
- 2. Set the EECON1 register for the erase operation:
  - set EEPGD bit to point to program memory;
  - clear the CFGS bit to access program memory;
  - set WREN bit to enable writes;
  - set FREE bit to enable the erase.

# 6.5 Writing to Flash Program Memory

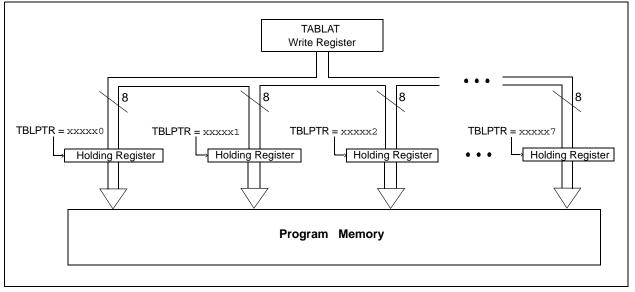

The programming block size is 4 words or 8 bytes. Word or byte programming is not supported.

Table writes are used internally to load the holding registers needed to program the Flash memory. There are 8 holding registers used by the table writes for programming.

Since the Table Latch (TABLAT) is only a single byte, the TBLWT instruction must be executed 8 times for each programming operation. All of the table write operations will essentially be short writes, because only the holding registers are written. At the end of updating 8 registers, the EECON1 register must be written to, to start the programming operation with a long write.

The long write is necessary for programming the internal Flash. Instruction execution is halted while in a long write cycle. The long write will be terminated by the internal programming timer.

#### FIGURE 6-5: TABLE WRITES TO FLASH PROGRAM MEMORY

# 6.5.1 FLASH PROGRAM MEMORY WRITE SEQUENCE

The sequence of events for programming an internal program memory location should be:

- 1. Read 64 bytes into RAM.
- 2. Update data values in RAM as necessary.
- 3. Load Table Pointer with address being erased.
- 4. Do the row erase procedure (see Section 6.4.1 "Flash Program Memory Erase Sequence").
- 5. Load Table Pointer with address of first byte being written.
- 6. Write the first 8 bytes into the holding registers with auto-increment.
- 7. Set the EECON1 register for the write operation:
  - set EEPGD bit to point to program memory;
  - clear the CFGS bit to access program memory;
  - set WREN bit to enable byte writes.

- 8. Disable interrupts.
- 9. Write 55h to EECON2.
- 10. Write AAh to EECON2.
- 11. Set the WR bit. This will begin the write cycle.
- 12. The CPU will stall for duration of the write (about 2 ms using internal timer).
- 13. Execute a NOP.
- 14. Re-enable interrupts.
- 15. Repeat steps 6-14 seven times to write 64 bytes.
- 16. Verify the memory (table read).

This procedure will require about 18 ms to update one row of 64 bytes of memory. An example of the required code is given in Example 6-3.

#### 6.5.2 WRITE VERIFY

Depending on the application, good programming practice may dictate that the value written to the memory should be verified against the original value. This should be used in applications where excessive writes can stress bits near the specification limit.

# 6.5.3 UNEXPECTED TERMINATION OF WRITE OPERATION

If a write is terminated by an unplanned event, such as loss of power or an unexpected Reset, the memory location just programmed should be verified and reprogrammed if needed. The WRERR bit is set when a write operation is interrupted by a MCLR Reset, or a WDT Time-out Reset during normal operation. In these situations, users can check the WRERR bit and rewrite the location.

### 6.6 Flash Program Operation During Code Protection

See **Section 19.0 "Special Features of the CPU"** for details on code protection of Flash program memory.

**Legend:** x = unknown, u = unchanged, - = unimplemented, read as '0'. Shaded cells are not used during Flash/EEPROM access.

# PIC18F1220/1320

NOTES:

# 7.0 DATA EEPROM MEMORY

The data EEPROM is readable and writable during normal operation over the entire VDD range. The data memory is not directly mapped in the register file space. Instead, it is indirectly addressed through the Special Function Registers (SFR).

There are four SFRs used to read and write the program and data EEPROM memory. These registers are:

- EECON1
- EECON2
- EEDATA
- EEADR

The EEPROM data memory allows byte read and write. When interfacing to the data memory block, EEDATA holds the 8-bit data for read/write and EEADR holds the address of the EEPROM location being accessed. These devices have 256 bytes of data EEPROM with an address range from 00h to FFh.

The EEPROM data memory is rated for high erase/ write cycle endurance. A byte write automatically erases the location and writes the new data (erasebefore-write). The write time is controlled by an on-chip timer. The write time will vary with voltage and temperature, as well as from chip to chip. Please refer to parameter D122 (Table 22-1 in **Section 22.0 "Electrical Characteristics"**) for exact limits.

# 7.1 EEADR

The address register can address 256 bytes of data EEPROM.

# 7.2 EECON1 and EECON2 Registers

EECON1 is the control register for memory accesses.

EECON2 is not a physical register. Reading EECON2 will read all '0's. The EECON2 register is used exclusively in the memory write and erase sequences.

Control bit, EEPGD, determines if the access will be to program or data EEPROM memory. When clear, operations will access the data EEPROM memory. When set, program memory is accessed. Control bit, CFGS, determines if the access will be to the configuration registers or to program memory/data EEPROM memory. When set, subsequent operations access configuration registers. When CFGS is clear, the EEPGD bit selects either program Flash or data EEPROM memory.

The WREN bit enables and disables erase and write operations. When set, erase and write operations are allowed. When clear, erase and write operations are disabled – the WR bit cannot be set while the WREN bit is clear. This mechanism helps to prevent accidental writes to memory due to errant (unexpected) code execution.

Firmware should keep the WREN bit clear at all times, except when starting erase or write operations. Once firmware has set the WR bit, the WREN bit may be cleared. Clearing the WREN bit will not affect the operation in progress.

The WRERR bit is set when a write operation is interrupted by a Reset. In these situations, the user can check the WRERR bit and rewrite the location. It is necessary to reload the data and address registers (EEDATA and EEADR), as these registers have cleared as a result of the Reset.

Control bits, RD and WR, start read and erase/write operations, respectively. These bits are set by firmware and cleared by hardware at the completion of the operation.

The RD bit cannot be set when accessing program memory (EEPGD = 1). Program memory is read using table read instructions. See **Section 6.1 "Table Reads and Table Writes"** regarding table reads.

Note: Interrupt flag bit, EEIF in the PIR2 register, is set when write is complete. It must be cleared in software.

## 7.3 Reading the Data EEPROM Memory

To read a data memory location, the user must write the address to the EEADR register, clear the EEPGD control bit (EECON1<7>) and then set control bit, RD (EECON1<0>). The data is available for the very next instruction cycle; therefore, the EEDATA register can be read by the next instruction. EEDATA will hold this value until another read operation, or until it is written to by the user (during a write operation).

## 7.4 Writing to the Data EEPROM Memory

To write an EEPROM data location, the address must first be written to the EEADR register and the data written to the EEDATA register. The sequence in Example 7-2 must be followed to initiate the write cycle.

The write will not begin if this sequence is not exactly followed (write 55h to EECON2, write AAh to EECON2, then set WR bit) for each byte. It is strongly recommended that interrupts be disabled during this code segment.

Additionally, the WREN bit in EECON1 must be set to enable writes. This mechanism prevents accidental writes to data EEPROM due to unexpected code execution (i.e., runaway programs). The WREN bit should be kept clear at all times, except when updating the EEPROM. The WREN bit is not cleared by hardware.

### EXAMPLE 7-1: DATA EEPROM READ

MOVLW DATA\_EE\_ADDR MOVWF EEADR BCF EECON1, EEPGD BSF EECON1, RD MOVF EEDATA, W

EXAMPLE 7-2:

; ; Data Memory Address to read ; Point to DATA memory ; EEPROM Read

; W = EEDATA

DATA EEPROM WRITE

After a write sequence has been initiated, EECON1, EEADR and EEDATA cannot be modified. The WR bit will be inhibited from being set unless the WREN bit is set. The WREN bit must be set on a previous instruction. Both WR and WREN cannot be set with the same instruction.

At the completion of the write cycle, the WR bit is cleared in hardware and the EEPROM Interrupt Flag bit (EEIF) is set. The user may either enable this interrupt or poll this bit. EEIF must be cleared by software.

# 7.5 Write Verify

Depending on the application, good programming practice may dictate that the value written to the memory should be verified against the original value. This should be used in applications where excessive writes can stress bits near the specification limit.

# 7.6 Protection Against Spurious Write

There are conditions when the device may not want to write to the data EEPROM memory. To protect against spurious EEPROM writes, various mechanisms have been built-in. On power-up, the WREN bit is cleared. Also, the Power-up Timer (72 ms duration) prevents EEPROM write.

The write initiate sequence and the WREN bit together help prevent an accidental write during brown-out, power glitch or software malfunction.

	BCF	EECON1, WREN	; Disable writes

# 7.7 Operation During Code-Protect

Data EEPROM memory has its own code-protect bits in configuration words. External read and write operations are disabled if either of these mechanisms are enabled.

The microcontroller itself can both read and write to the internal data EEPROM, regardless of the state of the code-protect configuration bit. Refer to Section 19.0 "Special Features of the CPU" for additional information.

## 7.8 Using the Data EEPROM

The data EEPROM is a high endurance, byte addressable array that has been optimized for the storage of frequently changing information (e.g., program variables or other data that are updated often). Frequently changing values will typically be updated more often than specification D124. If this is not the case, an array refresh must be performed. For this reason, variables that change infrequently (such as constants, IDs, calibration, etc.) should be stored in Flash program memory.

A simple data EEPROM refresh routine is shown in Example 7-3.

**Note:** If data EEPROM is only used to store constants and/or data that changes rarely, an array refresh is likely not required. See specification D124.

#### 8.0 **8 x 8 HARDWARE MULTIPLIER**

#### 8.1 Introduction

An 8 x 8 hardware multiplier is included in the ALU of the PIC18F1220/1320 devices. By making the multiply a hardware operation, it completes in a single instruction cycle. This is an unsigned multiply that gives a 16-bit result. The result is stored into the 16-bit product register pair (PRODH:PRODL). The multiplier does not affect any flags in the Status register.

Making the 8 x 8 multiplier execute in a single cycle gives the following advantages:

- Higher computational throughput
- · Reduces code size requirements for multiply algorithms

The performance increase allows the device to be used in applications previously reserved for Digital Signal Processors.

Table 8-1 shows a performance comparison between Enhanced devices using the single-cycle hardware multiply and performing the same function without the hardware multiply.

_		Program	Cycles	Time		
Routine	Multiply Method	Memory (Words)	(Max)	@ 40 MHz	@ 10 MHz	@ 4 MHz
9 x 9 uppigpod	Without hardware multiply	13	69	6.9 μs	27.6 µs	69 µs
8 x 8 unsigned	Hardware multiply	1	1	100 ns	400 ns	1 μs
	Without hardware multiply	33	91	9.1 μs	36.4 μs	91 μs
8 x 8 signed	Hardware multiply	6	6	600 ns	2.4 μs	6 µs
	Without hardware multiply	21	242	24.2 μs	96.8 µs	242 μs
16 x 16 unsigned	Hardware multiply	28	28	2.8 μs	11.2 μs	28 µs
16 v 16 signed	Without hardware multiply	52	254	25.4 μs	102.6 μs	254 μs
16 x 16 signed	Hardware multiply	35	40	4 μs	16 µs	40 µs

#### **TABLE 8-1:** PERFORMANCE COMPARISON

#### 8.2 Operation

Example 8-1 shows the sequence to do an 8 x 8 unsigned multiply. Only one instruction is required when one argument of the multiply is already loaded in the WREG register.

Example 8-2 shows the sequence to do an 8 x 8 signed multiply. To account for the sign bits of the arguments, each argument's Most Significant bit (MSb) is tested and the appropriate subtractions are done.

	:		

The PIC18F1220/1320 devices have multiple interrupt sources and an interrupt priority feature that allows each interrupt source to be assigned a high priority level or a low priority level. The high priority interrupt vector is at 000008h and the low priority interrupt vector is at 000018h. High priority interrupt events will interrupt any low priority interrupts that may be in progress.

There are ten registers which are used to control interrupt operation. These registers are:

- RCON
- INTCON
- INTCON2
- INTCON3
- PIR1, PIR2
- PIE1, PIE2
- IPR1, IPR2

It is recommended that the Microchip header files supplied with MPLAB<sup>®</sup> IDE be used for the symbolic bit names in these registers. This allows the assembler/ compiler to automatically take care of the placement of these bits within the specified register.

In general, each interrupt source has three bits to control its operation. The functions of these bits are:

- Flag bit to indicate that an interrupt event occurred
- Enable bit that allows program execution to branch to the interrupt vector address when the flag bit is set
- Priority bit to select high priority or low priority (INT0 has no priority bit and is always high priority)

The interrupt priority feature is enabled by setting the IPEN bit (RCON<7>). When interrupt priority is enabled, there are two bits which enable interrupts globally. Setting the GIEH bit (INTCON<7>) enables all interrupts that have the priority bit set (high priority). Setting the GIEL bit (INTCON<6>) enables all interrupts that have the priority bit cleared (low priority). When the interrupt flag, enable bit and appropriate global interrupt enable bit are set, the interrupt will vector immediately to address 00008h or 000018h, depending on the priority bit setting. Individual interrupts can be disabled through their corresponding enable bits.

When the IPEN bit is cleared (default state), the interrupt priority feature is disabled and interrupts are compatible with PICmicro mid-range devices. In Compatibility mode, the interrupt priority bits for each source have no effect. INTCON<6> is the PEIE bit, which enables/disables all peripheral interrupt sources. INTCON<7> is the GIE bit, which enables/disables all interrupt sources. All interrupts branch to address 000008h in Compatibility mode.

When an interrupt is responded to, the global interrupt enable bit is cleared to disable further interrupts. If the IPEN bit is cleared, this is the GIE bit. If interrupt priority levels are used, this will be either the GIEH or GIEL bit. High priority interrupt sources can interrupt a low priority interrupt. Low priority interrupts are not processed while high priority interrupts are in progress.

The return address is pushed onto the stack and the PC is loaded with the interrupt vector address (000008h or 000018h). Once in the Interrupt Service Routine, the source(s) of the interrupt can be determined by polling the interrupt flag bits. The interrupt flag bits must be cleared in software before re-enabling interrupts to avoid recursive interrupts.

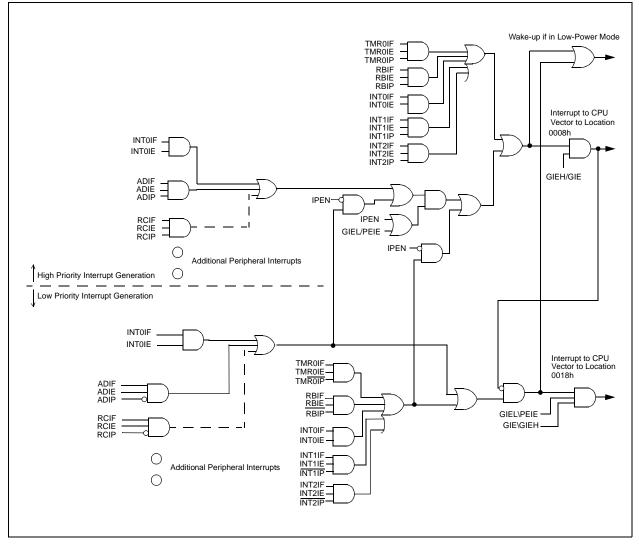

The "return from interrupt" instruction, RETFIE, exits the interrupt routine and sets the GIE bit (GIEH or GIEL, if priority levels are used), which re-enables interrupts.

For external interrupt events, such as the INT pins or the PORTB input change interrupt, the interrupt latency will be three to four instruction cycles. The exact latency is the same for one or two-cycle instructions. Individual interrupt flag bits are set, regardless of the status of their corresponding enable bit or the GIE bit.

**Note:** Do not use the MOVFF instruction to modify any of the interrupt control registers while **any** interrupt is enabled. Doing so may cause erratic microcontroller behavior.

# PIC18F1220/1320

#### 9.1 INTCON Registers

The INTCON registers are readable and writable registers, which contain various enable, priority and flag bits.

Note:	Interrupt flag bits are set when an interrupt
	condition occurs, regardless of the state of
	its corresponding enable bit or the global
	interrupt enable bit. User software should
	ensure the appropriate interrupt flag bits
	are clear prior to enabling an interrupt.
	This feature allows for software polling.

#### REGISTER 9-1: INTCON REGISTER

## 9.5 RCON Register

The RCON register contains bits used to determine the cause of the last Reset or wake-up from a low-power mode. RCON also contains the bit that enables interrupt priorities (IPEN).

#### 9.6 INTn Pin Interrupts

External interrupts on the RB0/INT0, RB1/INT1 and RB2/INT2 pins are edge-triggered: either rising if the corresponding INTEDGx bit is set in the INTCON2 register, or falling if the INTEDGx bit is clear. When a valid edge appears on the RBx/INTx pin, the corresponding flag bit, INTxF, is set. This interrupt can be disabled by clearing the corresponding enable bit, INTxE. Flag bit, INTxF, must be cleared in software in the Interrupt Service Routine before re-enabling the interrupt. All external interrupts (INT0, INT1 and INT2) can wake-up the processor from low-power modes if bit INTxE was set prior to going into low-power modes. If the Global Interrupt Enable bit, GIE, is set, the processor will branch to the interrupt vector following wake-up.

Interrupt priority for INT1 and INT2 is determined by the value contained in the interrupt priority bits, INT1IP (INTCON3<6>) and INT2IP (INTCON3<7>). There is no priority bit associated with INT0. It is always a high priority interrupt source.

#### 9.7 TMR0 Interrupt

In 8-bit mode (which is the default), an overflow (FFh  $\rightarrow$  00h) in the TMR0 register will set flag bit, TMR0IF. In 16-bit mode, an overflow (FFFFh  $\rightarrow$  0000h) in the TMR0H:TMR0L registers will set flag bit, TMR0IF. The interrupt can be enabled/disabled by setting/clearing enable bit, TMR0IE (INTCON<5>). Interrupt priority for Timer0 is determined by the value contained in the interrupt priority bit, TMR0IP (INTCON2<2>). See Section 11.0 "Timer0 Module" for further details on the Timer0 module.

#### 9.8 PORTB Interrupt-on-Change

An input change on PORTB<7:4> sets flag bit, RBIF (INTCON<0>). The interrupt can be enabled/disabled by setting/clearing enable bit, RBIE (INTCON<3>). Interrupt priority for PORTB interrupt-on-change is determined by the value contained in the interrupt priority bit, RBIP (INTCON2<0>).

#### 9.9 Context Saving During Interrupts

During interrupts, the return PC address is saved on the stack. Additionally, the WREG, Status and BSR registers are saved on the fast return stack. If a fast return from interrupt is not used (see **Section 5.3 "Fast Register Stack"**), the user may need to save the WREG, Status and BSR registers on entry to the Interrupt Service Routine. Depending on the user's application, other registers may also need to be saved. Example 9-1 saves and restores the WREG, Status and BSR registers during an Interrupt Service Routine.

EXAMPLE 9-1: SAVING STATUS, WREG AND BSR REGISTERS IN RAM

MOVWF MOVFF MOVFF	W_TEMP STATUS, STATUS_TEMP BSR, BSR_TEMP	;	W_TEMP is in virtual bank STATUS_TEMP located anywhere BSR_TMEP located anywhere
;			
; USER	ISR CODE		
;			
MOVFF	BSR_TEMP, BSR	;	Restore BSR
MOVF	W_TEMP, W	;	Restore WREG
MOVFF	STATUS_TEMP, STATUS	;	Restore STATUS

# PIC18F1220/1320

NOTES:

# 10.0 I/O PORTS

Depending on the device selected and features enabled, there are up to five ports available. Some pins of the I/O ports are multiplexed with an alternate function from the peripheral features on the device. In general, when a peripheral is enabled, that pin may not be used as a general purpose I/O pin.

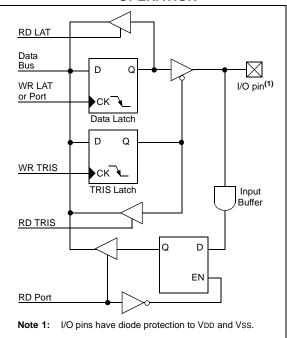

Each port has three registers for its operation. These registers are:

- TRIS register (data direction register)
- PORT register (reads the levels on the pins of the device)
- LAT register (output latch)

The Data Latch (LATA) register is useful for readmodify-write operations on the value that the I/O pins are driving.

A simplified model of a generic I/O port without the interfaces to other peripherals is shown in Figure 10-1.

## 10.1 PORTA, TRISA and LATA Registers

PORTA is an 8-bit wide, bidirectional port. The corresponding data direction register is TRISA. Setting a TRISA bit (= 1) will make the corresponding PORTA pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISA bit (= 0) will make the corresponding PORTA pin an output (i.e., put the contents of the output latch on the selected pin).

Reading the PORTA register reads the status of the pins, whereas writing to it will write to the port latch.

The Data Latch register (LATA) is also memory mapped. Read-modify-write operations on the LATA register read and write the latched output value for PORTA.

The RA4 pin is multiplexed with the Timer0 module clock input to become the RA4/T0CKI pin.

The sixth pin of PORTA ( $\overline{MCLR}/VPP/RA5$ ) is an input only pin. Its operation is controlled by the MCLRE configuration bit in Configuration Register 3H (CONFIG3H<7>). When selected as a port pin (MCLRE = 0), it functions as a digital input only pin; as such, it does not have TRIS or LAT bits associated with its operation. Otherwise, it functions as the device's Master Clear input. In either configuration, RA5 also functions as the programming voltage input during programming.

Note:	On a Power-on Reset, RA5 is enabled as a
	digital input only if Master Clear functionality
	is disabled.

Pins RA6 and RA7 are multiplexed with the main oscillator pins; they are enabled as oscillator or I/O pins by the selection of the main oscillator in Configuration Register 1H (see **Section 19.1 "Configuration Bits"** for details). When they are not used as port pins, RA6 and RA7 and their associated TRIS and LAT bits are read as '0'.

The other PORTA pins are multiplexed with analog inputs, the analog VREF+ and VREF- inputs and the LVD input. The operation of pins RA3:RA0 as A/D converter inputs is selected by clearing/setting the control bits in the ADCON1 register (A/D Control Register 1).

The RA4/T0CKI pin is a Schmitt Trigger input and an open-drain output. All other PORTA pins have TTL input levels and full CMOS output drivers.

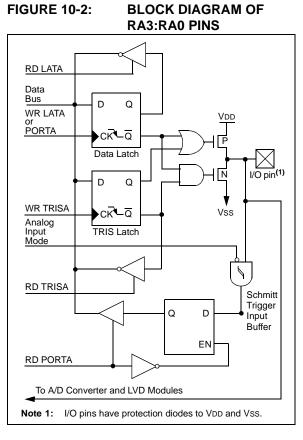

The TRISA register controls the direction of the RA pins, even when they are being used as analog inputs. The user must ensure the bits in the TRISA register are maintained set when using them as analog inputs.

#### EXAMPLE 10-1: INITIALIZING PORTA

	-	
CLRF	PORTA	; Initialize PORTA by
		; clearing output
		; data latches
CLRF	LATA	; Alternate method
		; to clear output
		; data latches
MOVLW	0x7F	; Configure A/D
MOVWF	ADCON1	; for digital inputs
MOVLW	0xD0	; Value used to
		; initialize data
		; direction
MOVWF	TRISA	; Set RA<3:0> as outputs
		; RA<7:4> as inputs

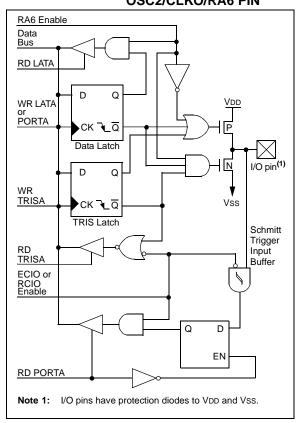

Note: On a Power-on Reset, RA3:RA0 are configured as analog inputs and read as '0'. RA4 is always a digital pin.

Legend: x = unknown, u = unchanged, - = unimplemented locations read as '0'. Shaded cells are not used by PORTA.

**Note 1:** RA7:RA6 and their associated latch and data direction bits are enabled as I/O pins based on oscillator configuration; otherwise, they are read as '0'.

2: RA5 is an input only if MCLR is disabled.

### 10.2 PORTB, TRISB and LATB Registers

PORTB is an 8-bit wide, bidirectional port. The corresponding data direction register is TRISB. Setting a TRISB bit (= 1) will make the corresponding PORTB pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISB bit (= 0) will make the corresponding PORTB pin an output (i.e., put the contents of the output latch on the selected pin).

The Data Latch register (LATB) is also memory mapped. Read-modify-write operations on the LATB register read and write the latched output value for PORTB.

CLRF	PORTB	; Initialize PORTB by ; clearing output
CLRF	LATB	; data latches ; Alternate method ; to clear output ; data latches
MOVLW MOVWF MOVLW	0x70 ADCON1 0xCF	; Set RB0, RB1, RB4 as ; digital I/O pins ; Value used to ; initialize data ; direction
MOVWF	TRISB	; Set RB<3:0> as inputs ; RB<5:4> as outputs ; RB<7:6> as inputs

Pins RB0-RB2 are multiplexed with INT0-INT2; pins RB0, RB1 and RB4 are multiplexed with A/D inputs; pins RB1 and RB4 are multiplexed with EUSART; and pins RB2, RB3, RB6 and RB7 are multiplexed with ECCP.

Each of the PORTB pins has a weak internal pull-up. A single control bit can turn on all the pull-ups. This is performed by clearing bit, RBPU (INTCON2<7>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on a Power-on Reset.

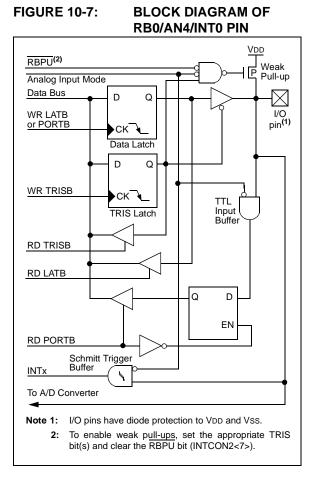

Note:	On a Power-on Reset, RB4:RB0 are
	configured as analog inputs by default and
	read as '0'; RB7:RB5 are configured as
	digital inputs.

Four of the PORTB pins (RB7:RB4) have an interrupton-change feature. Only pins configured as inputs can cause this interrupt to occur (i.e., any RB7:RB4 pin configured as an output is excluded from the interrupton-change comparison). The input pins (of RB7:RB4) are compared with the old value latched on the last read of PORTB. The "mismatch" outputs of RB7:RB4 are OR'ed together to generate the RB Port Change Interrupt with Flag bit, RBIF (INTCON<0>). This interrupt can wake the device from Sleep. The user, in the Interrupt Service Routine, can clear the interrupt in the following manner:

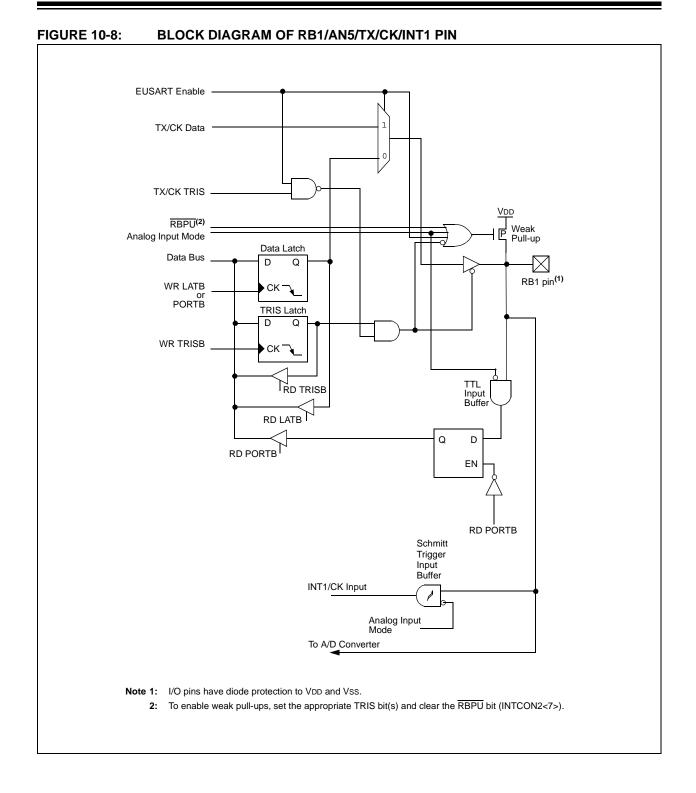

- a) Any read or write of PORTB (except with the MOVFF instruction). This will end the mismatch condition.
- b) Clear flag bit, RBIF.

A mismatch condition will continue to set flag bit, RBIF. Reading PORTB will end the mismatch condition and allow flag bit, RBIF, to be cleared.

The interrupt-on-change feature is recommended for wake-up on key depression operation and operations where PORTB is only used for the interrupt-on-change feature. Polling of PORTB is not recommended while using the interrupt-on-change feature.

# 11.0 TIMER0 MODULE

The Timer0 module has the following features:

- Software selectable as an 8-bit or 16-bit timer/ counter
- Readable and writable
- Dedicated 8-bit software programmable prescaler
- Clock source selectable to be external or internal
- Interrupt-on-overflow from FFh to 00h in 8-bit mode and FFFFh to 0000h in 16-bit mode
- · Edge select for external clock

Figure 11-1 shows a simplified block diagram of the Timer0 module in 8-bit mode and Figure 11-2 shows a simplified block diagram of the Timer0 module in 16-bit mode.

The T0CON register (Register 11-1) is a readable and writable register that controls all the aspects of Timer0, including the prescale selection.

#### FIGURE 11-1: TIMER0 BLOCK DIAGRAM IN 8-BIT MODE

# 11.1 Timer0 Operation

Timer0 can operate as a timer or as a counter.

Timer mode is selected by clearing the T0CS bit. In Timer mode, the Timer0 module will increment every instruction cycle (without prescaler). If the TMR0 register is written, the increment is inhibited for the following two instruction cycles. The user can work around this by writing an adjusted value to the TMR0 register.

Counter mode is selected by setting the T0CS bit. In Counter mode, Timer0 will increment either on every rising or falling edge of pin RA4/T0CKI. The incrementing edge is determined by the Timer0 Source Edge Select bit (T0SE). Clearing the T0SE bit selects the rising edge.

When an external clock input is used for Timer0, it must meet certain requirements. The requirements ensure the external clock can be synchronized with the internal phase clock (Tosc). Also, there is a delay in the actual incrementing of Timer0 after synchronization.

## 11.2 Prescaler

An 8-bit counter is available as a prescaler for the Timer0 module. The prescaler is not readable or writable.

The PSA and T0PS2:T0PS0 bits determine the prescaler assignment and prescale ratio.

Clearing bit PSA will assign the prescaler to the Timer0 module. When the prescaler is assigned to the Timer0 module, prescale values of 1:2, 1:4, ..., 1:256 are selectable.

When assigned to the Timer0 module, all instructions writing to the TMR0 register (e.g., CLRF TMR0, MOVWF TMR0, BSF TMR0, x, ..., etc.) will clear the prescaler count.

Note: Writing to TMR0 when the prescaler is assigned to Timer0 will clear the prescaler count, but will not change the prescaler assignment.

### 11.2.1 SWITCHING PRESCALER ASSIGNMENT

The prescaler assignment is fully under software control (i.e., it can be changed "on-the-fly" during program execution).

# 11.3 Timer0 Interrupt

The TMR0 interrupt is generated when the TMR0 register overflows from FFh to 00h in 8-bit mode, or FFFFh to 0000h in 16-bit mode. This overflow sets the TMR0IF bit. The interrupt can be masked by clearing the TMR0IE bit. The TMR0IF bit must be cleared in software by the Timer0 module Interrupt Service Routine before re-enabling this interrupt. The TMR0 interrupt cannot awaken the processor from Low-Power Sleep mode, since the timer requires clock cycles even when TOCS is set.

## 11.4 16-Bit Mode Timer Reads and Writes

TMR0H is not the high byte of the timer/counter in 16-bit mode, but is actually a buffered version of the high byte of Timer0 (refer to Figure 11-2). The high byte of the Timer0 counter/timer is not directly readable nor writable. TMR0H is updated with the contents of the high byte of Timer0 during a read of TMR0L. This provides the ability to read all 16 bits of Timer0, without having to verify that the read of the high and low byte were valid due to a rollover between successive reads of the high and low byte.

A write to the high byte of Timer0 must also take place through the TMR0H Buffer register. Timer0 high byte is updated with the contents of TMR0H when a write occurs to TMR0L. This allows all 16 bits of Timer0 to be updated at once.

TABLE 11-1:	<b>REGISTERS ASSOCIATED WITH TIMER0</b>

# PIC18F1220/1320

NOTES:

# 12.0 TIMER1 MODULE

The Timer1 module timer/counter has the following features:

- 16-bit timer/counter (two 8-bit registers: TMR1H and TMR1L)
- Readable and writable (both registers)
- Internal or external clock select
- Interrupt-on-overflow from FFFFh to 0000h
- · Reset from CCP module special event trigger
- Status of system clock operation

Figure 12-1 is a simplified block diagram of the Timer1 module.

Register 12-1 details the Timer1 Control register. This register controls the operating mode of the Timer1 module and contains the Timer1 Oscillator Enable bit (T1OSCEN). Timer1 can be enabled or disabled by setting or clearing control bit, TMR1ON (T1CON<0>).

The Timer1 oscillator can be used as a secondary clock source in power managed modes. When the T1RUN bit is set, the Timer1 oscillator is providing the system clock. If the Fail-Safe Clock Monitor is enabled and the Timer1 oscillator fails while providing the system clock, polling the T1RUN bit will indicate whether the clock is being provided by the Timer1 oscillator or another source.

Timer1 can also be used to provide Real-Time Clock (RTC) functionality to applications, with only a minimal addition of external components and code overhead.

# 12.1 Timer1 Operation

Timer1 can operate in one of these modes:

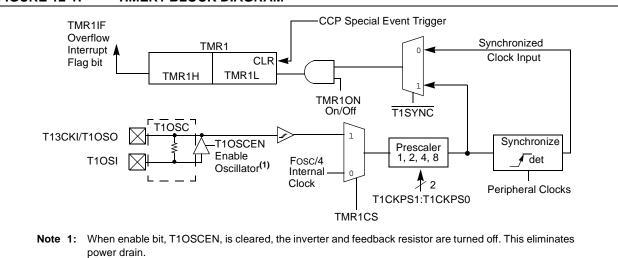

- As a timer
- As a synchronous counter
- · As an asynchronous counter

The operating mode is determined by the clock select bit, TMR1CS (T1CON<1>).

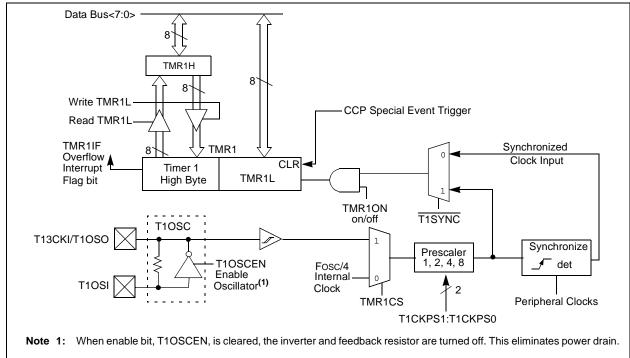

When TMR1CS = 0, Timer1 increments every instruction cycle. When TMR1CS = 1, Timer1 increments on every rising edge of the external clock input, or the Timer1 oscillator, if enabled.

When the Timer1 oscillator is enabled (T1OSCEN is set), the RB7/PGD/T1OSI/P1D/KBI3 and RB6/T1OSO/T13CKI/P1C/KBI2 pins become inputs. That is, the TRISB7:TRISB6 values are ignored and the pins read as '0'.

Timer1 also has an internal "Reset input". This Reset can be generated by the CCP module (see **Section 15.4.4 "Special Event Trigger"**).

# FIGURE 12-1: TIMER1 BLOCK DIAGRAM

# 12.2 Timer1 Oscillator

A crystal oscillator circuit is built-in between pins T1OSI (input) and T1OSO (amplifier output). It is enabled by setting control bit, T1OSCEN (T1CON<3>). The oscillator is a low-power oscillator rated for 32 kHz crystals. It will continue to run during all power managed modes. The circuit for a typical LP oscillator is shown in Figure 12-3. Table 12-1 shows the capacitor selection for the Timer1 oscillator.

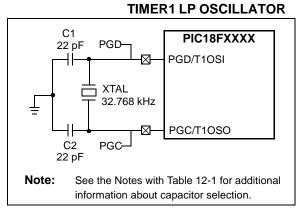

The user must provide a software time delay to ensure proper start-up of the Timer1 oscillator.

Note: The Timer1 oscillator shares the T1OSI and T1OSO pins with the PGD and PGC pins used for programming and debugging. When using the Timer1 oscillator, In-Circuit Serial Programming (ICSP) may not

function correctly (high voltage or low voltage), or the In-Circuit Debugger (ICD) may not communicate with the controller. As a result of using either ICSP or ICD, the Timer1 crystal may be damaged.

If ICSP or ICD operations are required, the crystal should be disconnected from the circuit (disconnect either lead), or installed after programming. The oscillator loading capacitors may remain in-circuit during ICSP or ICD operation.

# FIGURE 12-3: EXTERNAL COMPONENTS FOR THE

# TABLE 12-1:CAPACITOR SELECTION FOR<br/>THE TIMER OSCILLATOR

Osc Type	Freq	C1	C2	
LP	32 kHz	22 pF <sup>(1)</sup>	22 pF <sup>(1)</sup>	

Note 1: Microchip suggests this value as a starting point in validating the oscillator circuit. Oscillator operation should then be tested to ensure expected performance under all expected conditions (VDD and temperature).

- **2:** Higher capacitance increases the stability of the oscillator, but also increases the start-up time.
- Since each resonator/crystal has its own characteristics, the user should consult the resonator/crystal manufacturer for appropriate values of external components.
- 4: Capacitor values are for design guidance only.

### 12.3 Timer1 Oscillator Layout Considerations

The Timer1 oscillator circuit draws very little power during operation. Due to the low-power nature of the oscillator, it may also be sensitive to rapidly changing signals in close proximity.

The oscillator circuit, shown in Figure 12-3, should be located as close as possible to the microcontroller. There should be no circuits passing within the oscillator circuit boundaries other than VSS or VDD.

If a high-speed circuit must be located near the oscillator (such as the CCP1 pin in output compare or PWM mode, or the primary oscillator using the OSC2 pin), a grounded guard ring around the oscillator circuit, as shown in Figure 12-4, may be helpful when used on a single sided PCB, or in addition to a ground plane.

#### FIGURE 12-4: OSCILLATOR CIRCUIT WITH GROUNDED GUARD RING

# 12.5 Resetting Timer1 Using a CCP Trigger Output

If the CCP module is configured in Compare mode to generate a "special event trigger" (CCP1M3:CCP1M0 = 1011), this signal will reset Timer1 and start an A/D conversion, if the A/D module is enabled (see Section 15.4.4 "Special Event Trigger" for more information).

Timer1 must be configured for either Timer or Synchronized Counter mode to take advantage of this feature. If Timer1 is running in Asynchronous Counter mode, this Reset operation may not work.

In the event that a write to Timer1 coincides with a special event trigger from CCP1, the write will take precedence.

In this mode of operation, the CCPR1H:CCPR1L regis-

#### 12.4 Timer1 Interrupt

The TMR1 register pair (TMR1H:TMR1L) increments from 0000h to FFFFh and rolls over to 0000h. The Timer1 interrupt, if enabled, is generated on overflow, which is latched in interrupt flag bit, TMR1IF (PIR1<0>). This interrupt can be enabled/disabled by setting/clearing Timer1 Interrupt Enable bit, TMR1IE (PIE1<0>).

# 12.7 Using Timer1 as a Real-Time Clock

Adding an external LP oscillator to Timer1 (such as the one described in **Section 12.2 "Timer1 Oscillator**", above), gives users the option to include RTC functionality to their applications. This is accomplished with an inexpensive watch crystal to provide an accurate time base and several lines of application code to calculate the time. When operating in Sleep mode and using a battery or supercapacitor as a power source, it can completely eliminate the need for a separate RTC device and battery backup.

The application code routine, RTCisr, shown in Example 12-1, demonstrates a simple method to increment a counter at one-second intervals using an Interrupt Service Routine. Incrementing the TMR1 register pair to overflow, triggers the interrupt and calls the routine, which increments the seconds counter by one; additional counters for minutes and hours are incremented as the previous counter overflow.

Since the register pair is 16 bits wide, counting up to overflow the register directly from a 32.768 kHz clock would take 2 seconds. To force the overflow at the required one-second intervals, it is necessary to preload it; the simplest method is to set the MSb of TMR1H with a BSF instruction. Note that the TMR1L register is never preloaded or altered; doing so may introduce cumulative error over many cycles.

For this method to be accurate, Timer1 must operate in Asynchronous mode and the Timer1 overflow interrupt must be enabled (PIE1<0> = 1), as shown in the routine, RTCinit. The Timer1 oscillator must also be enabled and running at all times.

# 13.0 TIMER2 MODULE

The Timer2 module timer has the following features:

- 8-bit timer (TMR2 register)
- 8-bit period register (PR2)
- Readable and writable (both registers)
- Software programmable prescaler (1:1, 1:4, 1:16)
- Software programmable postscaler (1:1 to 1:16)
- Interrupt on TMR2 match with PR2

Timer2 has a control register shown in Register 13-1. TMR2 can be shut off by clearing control bit, TMR2ON (T2CON<2>), to minimize power consumption. Figure 13-1 is a simplified block diagram of the Timer2 module. Register 13-1 shows the Timer2 Control register. The prescaler and postscaler selection of Timer2 are controlled by this register.

# 13.1 Timer2 Operation

Timer2 can be used as the PWM time base for the PWM mode of the CCP module. The TMR2 register is readable and writable and is cleared on any device Reset. The input clock (Fosc/4) has a prescale option of 1:1, 1:4 or 1:16, selected by control bits, T2CKPS1:T2CKPS0 (T2CON<1:0>). The match output of TMR2 goes through a 4-bit postscaler (which gives a 1:1 to 1:16 scaling inclusive) to generate a TMR2 interrupt (latched in flag bit, TMR2IF (PIR1<1>)).

The prescaler and postscaler counters are cleared when any of the following occurs:

- · A write to the TMR2 register
- · A write to the T2CON register
- Any device Reset (Power-on Reset, MCLR Reset, Watchdog Timer Reset or Brown-out Reset)

TMR2 is not cleared when T2CON is written.

# 13.2 Timer2 Interrupt

The Timer2 module has an 8-bit period register, PR2. Timer2 increments from 00h until it matches PR2 and then resets to 00h on the next increment cycle. PR2 is a readable and writable register. The PR2 register is initialized to FFh upon Reset.

# 13.3 Output of TMR2

The output of TMR2 (before the postscaler) is fed to the Synchronous Serial Port module, which optionally uses it to generate the shift clock.

# 14.0 TIMER3 MODULE

The Timer3 module timer/counter has the following features:

- 16-bit timer/counter (two 8-bit registers; TMR3H and TMR3L)
- Readable and writable (both registers)
- Internal or external clock select
- Interrupt-on-overflow from FFFFh to 0000h
- Reset from CCP module trigger

Figure 14-1 is a simplified block diagram of the Timer3 module.

Register 14-1 shows the Timer3 Control register. This register controls the operating mode of the Timer3 module and sets the CCP clock source.

Register 12-1 shows the Timer1 Control register. This register controls the operating mode of the Timer1 module, as well as contains the Timer1 Oscillator Enable bit (T1OSCEN), which can be a clock source for Timer3.

#### REGISTER 14-1: T3CON: TIMER3 CONTROL REGISTER

# 14.1 Timer3 Operation

Timer3 can operate in one of these modes:

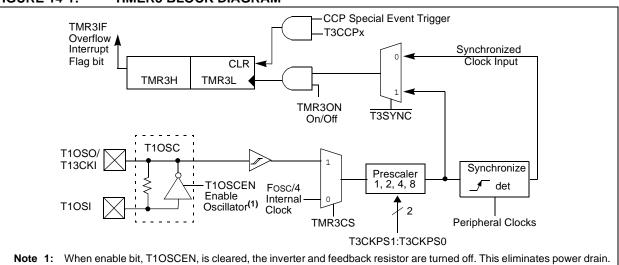

- As a timer
- As a synchronous counter
- As an asynchronous counter

The operating mode is determined by the clock select bit, TMR3CS (T3CON<1>).

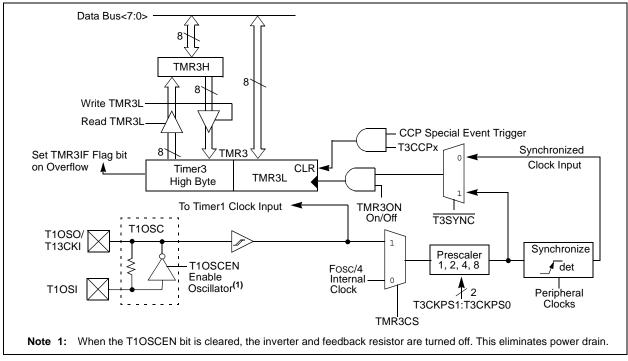

When TMR3CS = 0, Timer3 increments every instruction cycle. When TMR3CS = 1, Timer3 increments on every rising edge of the Timer1 external clock input or the Timer1 oscillator, if enabled.

When the Timer1 oscillator is enabled (T1OSCEN is set), the RB7/PGD/T1OSI/P1D/KBI3 and RB6/PGC/T1OSO/T13CKI/P1C/KBI2 pins become inputs. That is, the TRISB7:TRISB6 value is ignored and the pins are read as '0'.

Timer3 also has an internal "Reset input". This Reset can be generated by the CCP module (see **Section 15.4.4 "Special Event Trigger"**).

#### FIGURE 14-2: TIMER3 BLOCK DIAGRAM CONFIGURED IN 16-BIT READ/WRITE MODE

# FIGURE 14-1: TIMER3 BLOCK DIAGRAM

# 14.2 Timer1 Oscillator

The Timer1 oscillator may be used as the clock source for Timer3. The Timer1 oscillator is enabled by setting the T1OSCEN (T1CON<3>) bit. The oscillator is a lowpower oscillator rated for 32 kHz crystals. See **Section 12.2 "Timer1 Oscillator"** for further details.

# 14.3 Timer3 Interrupt

The TMR3 register pair (TMR3H:TMR3L) increments from 0000h to FFFFh and rolls over to 0000h. The TMR3 interrupt, if enabled, is generated on overflow, which is latched in interrupt flag bit, TMR3IF (PIR2<1>). This interrupt can be enabled/disabled by setting/clearing TMR3 Interrupt Enable bit, TMR3IE (PIE2<1>).

# 14.4 Resetting Timer3 Using a CCP Trigger Output

If the CCP module is configured in Compare mode to generate a "special event trigger" (CCP1M3:CCP1M0 = 1011), this signal will reset Timer3. See **Section 15.4.4 "Special Event Trigger"** for more information.

**Note:** The special event triggers from the CCP module will not set interrupt flag bit, TMR3IF (PIR1<0>).

Timer3 must be configured for either Timer or Synchronized Counter mode to take advantage of this feature. If Timer3 is running in Asynchronous Counter mode, this Reset operation may not work. In the event that a write to Timer3 coincides with a special event trigger from CCP1, the write will take precedence. In this mode of operation, the CCPR1H:CCPR1L register pair effectively becomes the period register for Timer3.

NOTES:

# 15.0 ENHANCED CAPTURE/ COMPARE/PWM (ECCP) MODULE

The Enhanced CCP module is implemented as a standard CCP module with Enhanced PWM capabilities. These capabilities allow for 2 or 4 output channels, user-selectable polarity, dead-band control and automatic shutdown and restart and are discussed in detail in **Section 15.5 "Enhanced PWM Mode"**.

The control register for CCP1 is shown in Register 15-1.

In addition to the expanded functions of the CCP1CON register, the ECCP module has two additional registers associated with Enhanced PWM operation and auto-shutdown features:

- PWM1CON
- ECCPAS

# 15.1 ECCP Outputs

The Enhanced CCP module may have up to four outputs, depending on the selected operating mode. These outputs, designated P1A through P1D, are multiplexed with I/O pins on PORTB. The pin assignments are summarized in Table 15-1.

To configure I/O pins as PWM outputs, the proper PWM mode must be selected by setting the P1Mn and CCP1Mn bits (CCP1CON<7:6> and <3:0>, respectively). The appropriate TRISB direction bits for the port pins must also be set as outputs.

ECCP Mode	CCP1CON Configuration	RB3	RB2	RB6	RB7
Compatible CCP	00xx 11xx	CCP1	RB2/INT2	RB6/PGC/T10SO/T13CKI/KBI2	RB7/PGD/T1OSI/KBI3
Dual PWM	10xx 11xx	P1A	P1B	RB6/PGC/T10SO/T13CKI/KBI2	RB7/PGD/T1OSI/KBI3
Quad PWM	xlxx llxx	P1A	P1B	P1C	P1D

**Legend:** x = Don't care. Shaded cells indicate pin assignments not used by ECCP in a given mode.

**Note 1:** TRIS register values must be configured appropriately.

# 15.2 CCP Module

Capture/Compare/PWM Register 1 (CCPR1) is comprised of two 8-bit registers: CCPR1L (low byte) and CCPR1H (high byte). The CCP1CON register controls the operation of CCP1. All are readable and writable.

#### TABLE 15-2: CCP MODE – TIMER RESOURCE

CCP Mode	Timer Resource
Capture	Timer1 or Timer3
Compare PWM	Timer1 or Timer3 Timer2

# 15.3 Capture Mode

In Capture mode, CCPR1H:CCPR1L captures the 16-bit value of the TMR1 or TMR3 registers when an event occurs on pin RB3/CCP1/P1A. An event is defined as one of the following:

- · every falling edge
- · every rising edge
- · every 4th rising edge
- every 16th rising edge

The event is selected by control bits, CCP1M3:CCP1M0 (CCP1CON<3:0>). When a capture is made, the interrupt request flag bit, CCP1IF (PIR1<2>), is set; it must be cleared in software. If another capture occurs before the value in register CCPR1 is read, the old captured value is overwritten by the new captured value.

#### 15.3.1 CCP PIN CONFIGURATION

In Capture mode, the RB3/CCP1/P1A pin should be configured as an input by setting the TRISB<3> bit.

Note:	If the RB3/CCP1/P1A is configured as an					
	output, a write to the port can cause a					
	capture condition.					

# 15.3.2 TIMER1/TIMER3 MODE SELECTION

The timers that are to be used with the capture feature (either Timer1 and/or Timer3) must be running in Timer mode or Synchronized Counter mode. In Asynchronous Counter mode, the capture operation may not work. The timer to be used with the CCP module is selected in the T3CON register.

# 15.3.3 SOFTWARE INTERRUPT

When the Capture mode is changed, a false capture interrupt may be generated. The user should keep bit, CCP1IE (PIE1<2>), clear while changing capture modes to avoid false interrupts and should clear the flag bit, CCP1IF, following any such change in operating mode.

#### 15.3.4 CCP PRESCALER

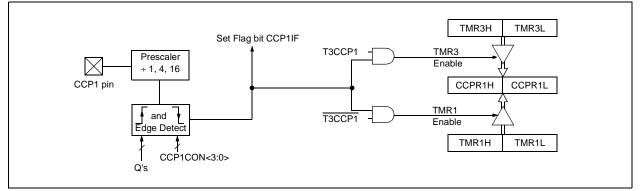

There are four prescaler settings, specified by bits CCP1M3:CCP1M0. Whenever the CCP module is turned off or the CCP module is not in Capture mode, the prescaler counter is cleared. This means that any Reset will clear the prescaler counter.

Switching from one capture prescaler to another may generate an interrupt. Also, the prescaler counter will not be cleared; therefore, the first capture may be from a non-zero prescaler. Example 15-1 shows the recommended method for switching between capture prescalers. This example also clears the prescaler counter and will not generate the "false" interrupt.

#### EXAMPLE 15-1: CHANGING BETWEEN CAPTURE PRESCALERS

CLRF	CCP1CON	; Turn CCP module off
MOVLW	NEW_CAPT_PS	; Load WREG with the
		; new prescaler mode
		; value and CCP ON
MOVWF	CCP1CON	; Load CCP1CON with
		; this value

# FIGURE 15-1: CAPTURE MODE OPERATION BLOCK DIAGRAM

# 15.4 Compare Mode

In Compare mode, the 16-bit CCPR1 register value is constantly compared against either the TMR1 register pair value, or the TMR3 register pair value. When a match occurs, the RB3/CCP1/P1A pin:

- Is driven high
- Is driven low
- Toggles output (high-to-low or low-to-high)
- Remains unchanged (interrupt only)

The action on the pin is based on the value of control bits, CCP1M3:CCP1M0. At the same time, interrupt flag bit, CCP1IF, is set.

# 15.4.1 CCP PIN CONFIGURATION

The user must configure the RB3/CCP1/P1A pin as an output by clearing the TRISB<3> bit.

Note: Clearing the CCP1CON register will force the RB3/CCP1/P1A compare output latch to the default low level. This is not the PORTB I/O data latch.

# 15.4.2 TIMER1/TIMER3 MODE SELECTION

Timer1 and/or Timer3 must be running in Timer mode or Synchronized Counter mode if the CCP module is using the compare feature. In Asynchronous Counter mode, the compare operation may not work.

# 15.4.3 SOFTWARE INTERRUPT MODE

When generate software interrupt is chosen, the RB3/ CCP1/P1A pin is not affected. CCP1IF is set and an interrupt is generated (if enabled).

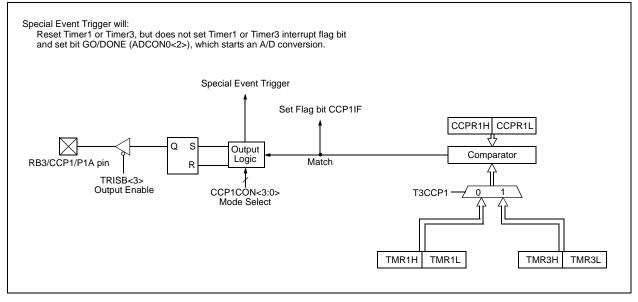

#### 15.4.4 SPECIAL EVENT TRIGGER

In this mode, an internal hardware trigger is generated, which may be used to initiate an action.

The special event trigger output of CCP1 resets the TMR1 register pair. This allows the CCPR1 register to effectively be a 16-bit programmable period register for Timer1.

The special event trigger also sets the GO/DONE bit (ADCON0<1>). This starts a conversion of the currently selected A/D channel if the A/D is on.

# 15.5 Enhanced PWM Mode

The Enhanced PWM Mode provides additional PWM output options for a broader range of control applications. The module is an upwardly compatible version of the standard CCP module and offers up to four outputs, designated P1A through P1D. Users are also able to select the polarity of the signal (either active-high or active-low). The module's output mode and polarity are configured by setting the P1M1:P1M0 and CCP1M3CCP1M0 bits of the CCP1CON register (CCP1CON<7:6> and CCP1CON<3:0>, respectively).

Figure 15-3 shows a simplified block diagram of PWM operation. All control registers are double-buffered and are loaded at the beginning of a new PWM cycle (the period boundary when Timer2 resets) in order to prevent glitches on any of the outputs. The exception is the PWM Delay register, ECCP1DEL, which is loaded at either the duty cycle boundary or the boundary period (whichever comes first). Because of the buffering, the module waits until the assigned timer resets instead of starting immediately. This means that Enhanced PWM waveforms, but are instead offset by one full instruction cycle (4 Tosc).

As before, the user must manually configure the appropriate TRIS bits for output.

#### 15.5.1 PWM PERIOD

The PWM period is specified by writing to the PR2 register. The PWM period can be calculated using the equation:

#### EQUATION 15-1: PWM PERIOD

PWM frequency is defined as 1/[PWM period]. When TMR2 is equal to PR2, the following three events occur on the next increment cycle:

- TMR2 is cleared
- The CCP1 pin is set (if PWM duty cycle = 0%, the CCP1 pin will not be set)
- The PWM duty cycle is copied from CCPR1L into CCPR1H

# 15.5.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the CCPR1L register and to the CCP1CON<5:4> bits. Up to 10-bit resolution is available. The CCPR1L contains the eight MSbs and the CCP1CON<5:4> contains the two LSbs. This 10-bit value is represented by CCPR1L:CCP1CON<5:4>. The PWM duty cycle is calculated by the equation:

#### EQUATION 15-2: PWM DUTY CYCLE

PWM Duty Cycle =	(CCPR1L:CCP1CON<5:4>) •
	TOSC • (TMR2 Prescale Value)

CCPR1L and CCP1CON<5:4> can be written to at any time, but the duty cycle value is not copied into CCPR1H until a match between PR2 and TMR2 occurs (i.e., the period is complete). In PWM mode, CCPR1H is a read-only register.

The CCPR1H register and a 2-bit internal latch are used to double-buffer the PWM duty cycle. This double-buffering is essential for glitchless PWM operation. When the CCPR1H and 2-bit latch match TMR2, concatenated with an internal 2-bit Q clock or two bits of the TMR2 prescaler, the CCP1 pin is cleared. The maximum PWM resolution (bits) for a given PWM frequency is given by the equation:

#### **EQUATION 15-3: PWM RESOLUTION**

PWM Resolution (max) =	$\log\left(\frac{FOSC}{FPWM}\right)$ bits
i www.kesolution(inax) =	log(2)

Note: If the PWM duty cycle value is longer than the PWM period, the CCP1 pin will not be cleared.

# 15.5.3 PWM OUTPUT CONFIGURATIONS

The P1M1:P1M0 bits in the CCP1CON register allow one of four configurations:

- Single Output
- Half-Bridge Output
- Full-Bridge Output, Forward mode
- Full-Bridge Output, Reverse mode

The Single Output mode is the Standard PWM mode discussed in **Section 15.5** "Enhanced PWM Mode". The Half-Bridge and Full-Bridge Output modes are covered in detail in the sections that follow.

The general relationship of the outputs in all configurations is summarized in Figure 15-4.

# TABLE 15-4: EXAMPLE PWM FREQUENCIES AND RESOLUTIONS AT 40 MHz

PWM Frequency	2.44 kHz	9.77 kHz	39.06 kHz	156.25 kHz	312.50 kHz	416.67 kHz
Timer Prescaler (1, 4, 16)	16	4	1	1	1	1
PR2 Value	FFh	FFh	FFh	3Fh	1Fh	17h
Maximum Resolution (bits)	10	10	10	8	7	6.58

Note: The Timer2 postscaler (see Section 13.0 "Timer2 Module") is not used in the determination of the PWM frequency. The postscaler could be used to have a servo update rate at a different frequency than the PWM output.

FIGURE 15-3: SIMPLIFIED BLOCK DIAGRAM OF THE ENHANCED PWM MODULE

#### **PWM OUTPUT RELATIONSHIPS (ACTIVE-LOW STATE) FIGURE 15-5:**

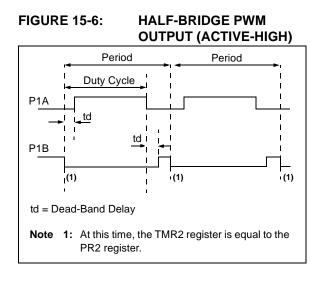

Duty Cycle = Tosc \* (CCPR1L<7:0>:CCP1CON<5:4>) \* (TMR2 Prescale Value)
Delay = 4 \* Tosc \* (PWM1CON<6:0>)

Note 1: Dead-band delay is programmed using the PWM1CON register (Section 15.5.6 "Programmable Dead-Band Delay").

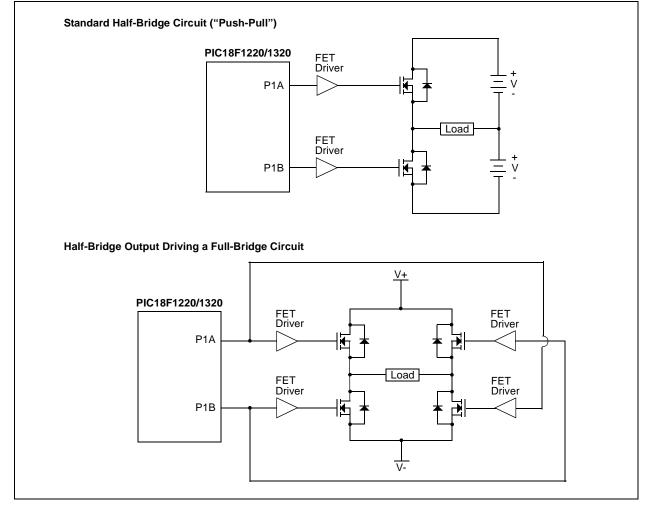

# 15.5.4 HALF-BRIDGE MODE

In the Half-Bridge Output mode, two pins are used as outputs to drive push-pull loads. The PWM output signal is output on the RB3/CCP1/P1A pin, while the complementary PWM output signal is output on the RB2/P1B/INT2 pin (Figure 15-6). This mode can be used for half-bridge applications, as shown in Figure 15-7, or for full-bridge applications, where four power switches are being modulated with two PWM signals.

In Half-Bridge Output mode, the programmable deadband delay can be used to prevent shoot-through current in half-bridge power devices. The value of bits, PDC6:PDC0 (PWM1CON<6:0>), sets the number of instruction cycles before the output is driven active. If the value is greater than the duty cycle, the corresponding output remains inactive during the entire cycle. See **Section 15.5.6 "Programmable Dead-Band Delay"** for more details of the dead-band delay operations. The TRISB<3> and TRISB<2> bits must be cleared to configure P1A and P1B as outputs.

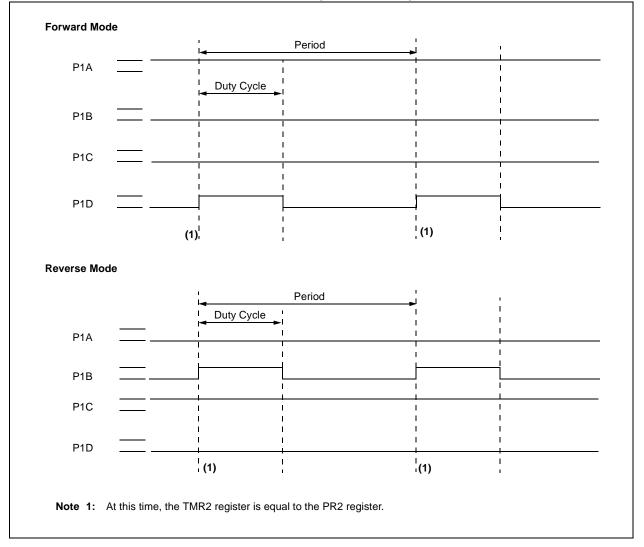

# FIGURE 15-7: EXAMPLES OF HALF-BRIDGE OUTPUT MODE APPLICATIONS

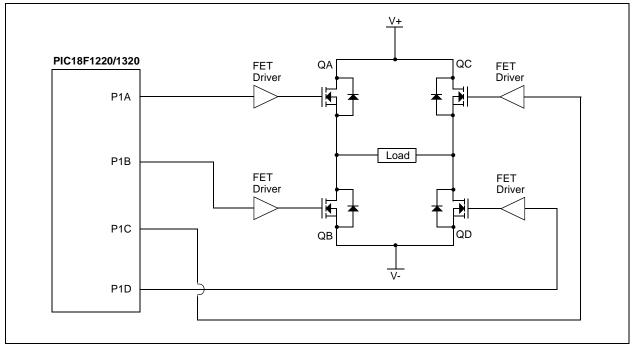

#### 15.5.5 FULL-BRIDGE MODE

In Full-Bridge Output mode, four pins are used as outputs; however, only two outputs are active at a time. In the Forward mode, pin RB3/CCP1/P1A is continuously active and pin RB7/PGD/T10SI/P1D/KBI3 is modulated. In the Reverse mode, pin RB6/PGC/T10S0/T13CKI/P1C/KBI2 is continuously active and pin RB2/P1B/INT2 is modulated. These are illustrated in Figure 15-8.

#### FIGURE 15-9: EXAMPLE OF FULL-BRIDGE APPLICATION

# 15.5.5.1 Direction Change in Full-Bridge Mode

In the Full-Bridge Output mode, the P1M1 bit in the CCP1CON register allows the user to control the Forward/Reverse direction. When the application firmware changes this direction control bit, the module will assume the new direction on the next PWM cycle.

Just before the end of the current PWM period, the modulated outputs (P1B and P1D) are placed in their inactive state, while the unmodulated outputs (P1A and P1C) are switched to drive in the opposite direction. This occurs in a time interval of (4 Tosc \* (Timer2 Prescale Value) before the next PWM period begins. The Timer2 prescaler will be either 1,4 or 16, depending on the value of the T2CKPS bit (T2CON<1:0>). During the interval from the switch of the unmodulated outputs to the beginning of the next period, the modulated outputs (P1B and P1D) remain inactive. This relationship is shown in Figure 15-10.

Note that in the Full-Bridge Output mode, the ECCP module does not provide any dead-band delay. In general, since only one output is modulated at all times, dead-band delay is not required. However, there is a situation where a dead-band delay might be required. This situation occurs when both of the following conditions are true:

- 1. The direction of the PWM output changes when the duty cycle of the output is at or near 100%.
- 2. The turn-off time of the power switch, including the power device and driver circuit, is greater than the turn-on time.

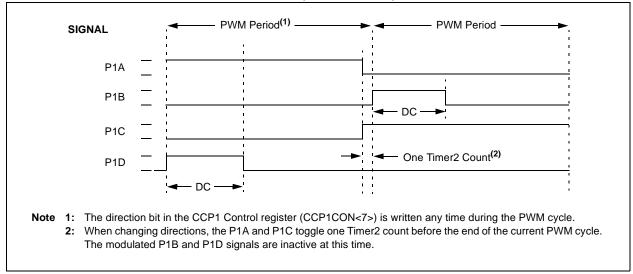

Figure 15-11 shows an example where the PWM direction changes from forward to reverse, at a near 100% duty cycle. At time t1, the output P1A and P1D become inactive, while output P1C becomes active. In this example, since the turn-off time of the power devices is longer than the turn-on time, a shoot-through current may flow through power devices QC and QD (see Figure 15-9) for the duration of 't'. The same phenomenon will occur to power devices QA and QB for PWM direction change from reverse to forward.

If changing PWM direction at high duty cycle is required for an application, one of the following requirements must be met:

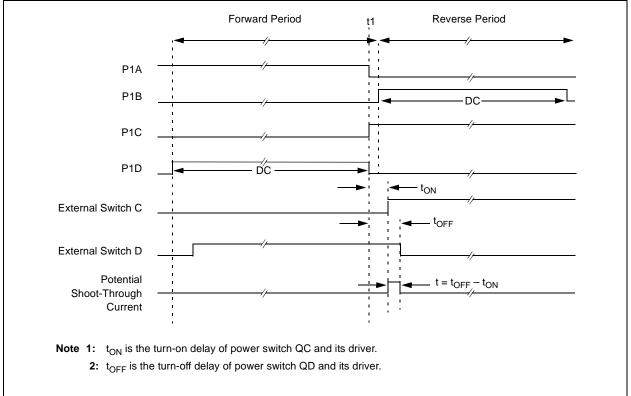

- 1. Reduce PWM for a PWM period before changing directions.
- 2. Use switch drivers that can drive the switches off faster than they can drive them on.

Other options to prevent shoot-through current may exist.

#### 15.5.6 PROGRAMMABLE DEAD-BAND DELAY

In half-bridge applications where all power switches are modulated at the PWM frequency at all times, the power switches normally require more time to turn off than to turn on. If both the upper and lower power switches are switched at the same time (one turned on and the other turned off), both switches may be on for a short period of time until one switch completely turns off. During this brief interval, a very high current (shootthrough current) may flow through both power switches, shorting the bridge supply. To avoid this potentially destructive shoot-through current from flowing during switching, turning on either of the power switches is normally delayed to allow the other switch to completely turn off.

In the Half-Bridge Output mode, a digitally programmable dead-band delay is available to avoid shoot-through current from destroying the bridge power switches. The delay occurs at the signal transition from the non-active state to the active state. See Figure 15-6 for an illustration. The lower seven bits of the PWM1CON register (Register 15-2) sets the delay period in terms of microcontroller instruction cycles (TCY or 4 TOSC).

#### 15.5.7 ENHANCED PWM AUTO-SHUTDOWN

When the ECCP is programmed for any of the Enhanced PWM modes, the active output pins may be configured for auto-shutdown. Auto-shutdown immediately places the Enhanced PWM output pins into a defined shutdown state when a shutdown event occurs.

A shutdown event can be caused by the INT0, INT1 or INT2 pins (or any combination of these three sources). The auto-shutdown feature can be disabled by not selecting any auto-shutdown sources. The auto-shutdown sources to be used are selected using the ECCPAS2:ECCPAS0 bits (bits <6:4> of the ECCPAS register).

When a shutdown occurs, the output pins are asynchronously placed in their shutdown states, specified by the PSSAC1:PSSAC0 and PSSBD1:PSSBD0 bits (ECCPAS<3:0>). Each pin pair (P1A/P1C and P1B/P1D) may be set to drive high, drive low or be tristated (not driving). The ECCPASE bit (ECCPAS<7>) is also set to hold the Enhanced PWM outputs in their shutdown states.

The ECCPASE bit is set by hardware when a shutdown event occurs. If automatic restarts are not enabled, the ECCPASE bit is cleared by firmware when the cause of the shutdown clears. If automatic restarts are enabled, the ECCPASE bit is automatically cleared when the cause of the auto-shutdown has cleared.

If the ECCPASE bit is set when a PWM period begins, the PWM outputs remain in their shutdown state for that entire PWM period. When the ECCPASE bit is cleared, the PWM outputs will return to normal operation at the beginning of the next PWM period.

**Note:** Writing to the ECCPASE bit is disabled while a shutdown condition is active.

#### 15.5.7.1 Auto-Shutdown and Automatic Restart

The auto-shutdown feature can be configured to allow automatic restarts of the module, following a shutdown event. This is enabled by setting the PRSEN bit of the PWM1CON register (PWM1CON<7>).

In Shutdown mode with PRSEN = 1 (Figure 15-12), the ECCPASE bit will remain set for as long as the cause of the shutdown continues. When the shutdown condition clears, the ECCPASE bit is automatically cleared. If PRSEN = 0 (Figure 15-13), once a shutdown condition occurs, the ECCPASE bit will remain set until it is cleared by firmware. Once ECCPASE is cleared, the Enhanced PWM will resume at the beginning of the next PWM period.

Note:	Writing to the ECCPASE bit is disabled
	while a shutdown condition is active.

Independent of the PRSEN bit setting, the ECCPASE bit cannot be cleared as long as the cause of the shutdown persists.

The Auto-Shutdown mode can be forced by writing a '1' to the ECCPASE bit.

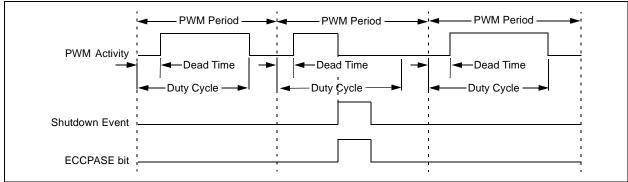

# 15.5.8 START-UP CONSIDERATIONS

When the ECCP module is used in the PWM mode, the application hardware must use the proper external pullup and/or pull-down resistors on the PWM output pins. When the microcontroller is released from Reset, all of the I/O pins are in the high-impedance state. The external circuits must keep the power switch devices in the off state, until the microcontroller drives the I/O pins with the proper signal levels, or activates the PWM output(s).

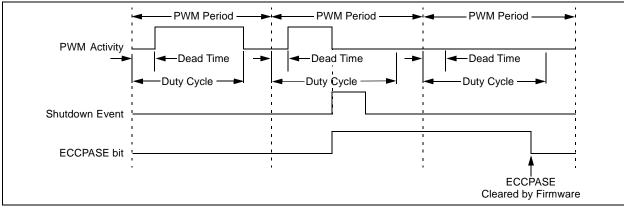

The CCP1M1:CCP1M0 bits (CCP1CON<1:0>) allow the user to choose whether the PWM output signals are active-high or active-low for each pair of PWM output pins (P1A/P1C and P1B/P1D). The PWM output polarities must be selected before the PWM pins are configured as outputs. Changing the polarity configuration while the PWM pins are configured as outputs is not recommended, since it may result in damage to the application circuits.

The P1A, P1B, P1C and P1D output latches may not be in the proper states when the PWM module is initialized. Enabling the PWM pins for output at the same time as the ECCP module may cause damage to the application circuit. The ECCP module must be enabled in the proper output mode and complete a full PWM cycle, before configuring the PWM pins as outputs. The completion of a full PWM cycle is indicated by the TMR2IF bit being set as the second PWM period begins.

# FIGURE 15-12: PWM AUTO-SHUTDOWN (PRSEN = 1, AUTO-RESTART ENABLED)

#### FIGURE 15-13: PWM AUTO-SHUTDOWN (PRSEN = 0, AUTO-RESTART DISABLED)

# 15.5.9 SETUP FOR PWM OPERATION

The following steps should be taken when configuring the ECCP1 module for PWM operation:

- 1. Configure the PWM pins P1A and P1B (and P1C and P1D, if used) as inputs by setting the corresponding TRISB bits.
- 2. Set the PWM period by loading the PR2 register.
- Configure the ECCP module for the desired PWM mode and configuration by loading the CCP1CON register with the appropriate values:
  - Select one of the available output configurations and direction with the P1M1:P1M0 bits.
  - Select the polarities of the PWM output signals with the CCP1M3:CCP1M0 bits.
- 4. Set the PWM duty cycle by loading the CCPR1L register and CCP1CON<5:4> bits.
- 5. For Half-Bridge Output mode, set the deadband delay by loading PWM1CON<6:0> with the appropriate value.
- 6. If auto-shutdown operation is required, load the ECCPAS register:
  - Select the auto-shutdown sources using the ECCPAS<2:0> bits.
  - Select the shutdown states of the PWM output pins using PSSAC1:PSSAC0 and PSSBD1:PSSBD0 bits.
  - Set the ECCPASE bit (ECCPAS<7>).
- 7. If auto-restart operation is required, set the PRSEN bit (PWM1CON<7>).
- 8. Configure and start TMR2:
  - Clear the TMR2 interrupt flag bit by clearing the TMR2IF bit (PIR1<1>).
  - Set the TMR2 prescale value by loading the T2CKPS bits (T2CON<1:0>).
  - Enable Timer2 by setting the TMR2ON bit (T2CON<2>).
- 9. Enable PWM outputs after a new PWM cycle has started:
  - Wait until TMR2 overflows (TMR2IF bit is set).
  - Enable the CCP1/P1A, P1B, P1C and/or P1D pin outputs by clearing the respective TRISB bits.
  - Clear the ECCPASE bit (ECCPAS<7>).

#### 15.5.10 OPERATION IN LOW-POWER MODES

In the Low-Power Sleep mode, all clock sources are disabled. Timer2 will not increment and the state of the module will not change. If the ECCP pin is driving a value, it will continue to drive that value. When the device wakes up, it will continue from this state. If Two-Speed Start-ups are enabled, the initial start-up frequency may not be stable if the INTOSC is being used.

In PRI\_IDLE mode, the primary clock will continue to clock the ECCP module without change.

In all other low-power modes, the selected low-power mode clock will clock Timer2. Other low-power mode clocks will most likely be different than the primary clock frequency.

#### 15.5.10.1 Operation with Fail-Safe Clock Monitor

If the Fail-Safe Clock Monitor is enabled (CONFIG1H<6> is programmed), a clock failure will force the device into the Low-Power RC\_RUN mode and the OSCFIF bit (PIR2<7>) will be set. The ECCP will then be clocked from the INTRC clock source, which may have a different clock frequency than the primary clock. By loading the IRCF2:IRCF0 bits on Resets, the user can enable the INTOSC at a high clock speed in the event of a clock failure.

See the previous section for additional details.

#### 15.5.11 EFFECTS OF A RESET

Both power-on and subsequent Resets will force all ports to input mode and the CCP registers to their Reset states.

This forces the Enhanced CCP module to reset to a state compatible with the standard CCP module.

#### **REGISTERS ASSOCIATED WITH ENHANCED PWM AND TIMER2 TABLE 15-5**:

Legend: x = unknown, u = unchanged, - = unimplemented, read as '0'.

Shaded cells are not used by the ECCP module in Enhanced PWM mode.

# 16.0 ENHANCED ADDRESSABLE UNIVERSAL SYNCHRONOUS ASYNCHRONOUS RECEIVER TRANSMITTER (EUSART)

The Enhanced Addressable Universal Synchronous Asynchronous Receiver Transmitter (EUSART) module can be configured as a full-duplex asynchronous system that can communicate with peripheral devices, such as CRT terminals and personal computers. It can also be configured as a half-duplex synchronous system that can communicate with peripheral devices, such as A/D or D/A integrated circuits, serial EEPROMs, etc.

The Enhanced Addressable USART module implements additional features, including automatic baud rate detection and calibration, automatic wake-up on Sync Break reception and 12-bit Break character transmit. These features make it ideally suited for use in Local Interconnect Network (LIN) bus systems.

The EUSART can be configured in the following modes:

- Asynchronous (full duplex) with:
  - Auto-wake-up on character reception
  - Auto-baud calibration
  - 12-bit Break character transmission
- Synchronous Master (half duplex) with selectable clock polarity
- Synchronous Slave (half duplex) with selectable clock polarity

The RB1/AN5/TX/CK/INT1 and RB4/AN6/RX/DT/KBI0 pins must be configured as follows for use with the Universal Synchronous Asynchronous Receiver Transmitter:

- SPEN (RCSTA<7>) bit must be set ( = 1),
- PCFG6:PCFG5 (ADCON1<5:6>) must be set ( = 1

# REGISTER 16-3: BAUDCTL: BAUD RATE CONTROL REGISTER

# 16.2 EUSART Baud Rate Generator (BRG)

The BRG is a dedicated 8-bit or 16-bit generator, that supports both the Asynchronous and Synchronous modes of the EUSART. By default, the BRG operates in 8-bit mode; setting the BRG16 bit (BAUDCTL<3>) selects 16-bit mode.

The SPBRGH:SPBRG register pair controls the period of a free running timer. In Asynchronous mode, bits BRGH (TXSTA<2>) and BRG16 also control the baud rate. In Synchronous mode, bit BRGH is ignored. Table 16-1 shows the formula for computation of the baud rate for different EUSART modes which only apply in Master mode (internally generated clock).

Given the desired baud rate and Fosc, the nearest integer value for the SPBRGH:SPBRG registers can be calculated using the formulas in Table 16-1. From this, the error in baud rate can be determined. An example calculation is shown in Example 16-1. Typical baud rates and error values for the various asynchronous modes are shown in Table 16-2. It may be advantageous to use the high baud rate (BRGH = 1), or the 16-bit BRG to reduce the baud rate error, or achieve a slow baud rate for a fast oscillator frequency.

Writing a new value to the SPBRGH:SPBRG registers causes the BRG timer to be reset (or cleared). This ensures the BRG does not wait for a timer overflow before outputting the new baud rate.

# 16.2.1 POWER MANAGED MODE OPERATION

The system clock is used to generate the desired baud rate; however, when a power managed mode is entered, the clock source may be operating at a different frequency than in PRI\_RUN mode. In Sleep mode, no clocks are present and in PRI\_IDLE mode, the primary clock source continues to provide clocks to the Baud Rate Generator; however, in other power managed modes, the clock frequency will probably change. This may require the value in SPBRG to be adjusted.

If the system clock is changed during an active receive operation, a receive error or data loss may result. To avoid this problem, check the status of the RCIDL bit and make sure that the receive operation is Idle before changing the system clock.

# 16.2.2 SAMPLING

The data on the RB4/AN6/RX/DT/KBI0 pin is sampled three times by a majority detect circuit to determine if a high or a low level is present at the RX pin.

C	Configuration Bits       SYNC     BRG16		PPC/EUSAPT Mode	Baud Rate Formula			
SYNC			BRG/EUSART Mode

# 16.2.3 AUTO-BAUD RATE DETECT

The Enhanced USART module supports the automatic detection and calibration of baud rate. This feature is active only in Asynchronous mode and while the WUE bit is clear.

The automatic baud rate measurement sequence (Figure 16-1) begins whenever a Start bit is received and the ABDEN bit is set. The calculation is self-averaging.

In the Auto-Baud Rate Detect (ABD) mode, the clock to the BRG is reversed. Rather than the BRG clocking the incoming RX signal, the RX signal is timing the BRG. In ABD mode, the internal Baud Rate Generator is used as a counter to time the bit period of the incoming serial byte stream.

Once the ABDEN bit is set, the state machine will clear the BRG and look for a Start bit. The Auto-Baud Detect must receive a byte with the value 55h (ASCII "U", which is also the LIN bus Sync character), in order to calculate the proper bit rate. The measurement is taken over both a low and a high bit time in order to minimize any effects caused by asymmetry of the incoming signal. After a Start bit, the SPBRG begins counting up using the preselected clock source on the first rising edge of RX. After eight bits on the RX pin, or the fifth rising edge, an accumulated value totalling the proper BRG period is left in the SPBRGH:SPBRG registers. Once the 5th edge is seen (should correspond to the Stop bit), the ABDEN bit is automatically cleared.

While calibrating the baud rate period, the BRG registers are clocked at 1/8th the preconfigured clock rate. Note that the BRG clock will be configured by the BRG16 and BRGH bits. Independent of the BRG16 bit setting, both the SPBRG and SPBRGH will be used as a 16-bit counter. This allows the user to verify that no carry occurred for 8-bit modes, by checking for 00h in the SPBRGH register. Refer to Table 16-4 for counter clock rates to the BRG.

While the ABD sequence takes place, the EUSART state machine is held in Idle. The RCIF interrupt is set once the fifth rising edge on RX is detected. The value in the RCREG needs to be read to clear the RCIF interrupt. RCREG content should be discarded.

Note 1: It is up to the user to determine that the incoming character baud rate is within the range of the selected BRG clock source. Some combinations of oscillator frequency and EUSART baud rates are not possible due to bit error rates. Overall system timing and communication baud rates must be taken into consideration when using the Auto-Baud Rate Detection feature.

#### 16.2.4 RECEIVING A SYNC (AUTO-BAUD RATE DETECT)

To receive a Sync (Auto-Baud Rate Detect):

- 1. Configure the EUSART for asynchronous receive. TXEN should remain clear. SPBRGH:SPBRG may be left as is. The controller should operate in either PRI\_RUN or PRI\_IDLE.
- 2. Enable RXIF interrupts. Set RCIE, PEIE, GIE.
- 3. Enable Auto-Baud Rate Detect. Set ABDEN.
- 4. When the next RCIF interrupt occurs, the received baud rate has been measured. Read RCREG to clear RCIF and discard. Check SPBRGH:SPBRG for a valid value. The EUSART is ready for normal communications. Return from the interrupt. Allow the primary clock to run (PRI\_RUN or PRI\_IDLE).
- Process subsequent RCIF interrupts normally as in asynchronous reception. Remain in PRI\_RUN or PRI\_IDLE until communications are complete.

#### TABLE 16-4: BRG COUNTER CLOCK RATES

BRG16	BRGH	BRG Counter Clock
0	0	Fosc/512
0	1	Fosc/128
1	0	Fosc/128
1	1	Fosc/32

**Note:** During the ABD sequence, SPBRG and SPBRGH are both used as a 16-bit counter, independent of BRG16 setting.

BRG Value	XXXXh	0000h		001Ch
RX pin		Start	Edge #1 _ Edge #2 _ Edge #3 _ Edge #4 Bit 0 _ Bit 1 _ Bit 2 _ Bit 3 _ Bit 4 _ Bit 5 _ Bit 6 _ B	Edge #5
BRG Clock		huuuuuu		
ABDEN bit	Set by User —			Auto-Cleared
RCIF bit (Interrupt)				
Read RCREG		 	1 1 1 1	
SPBRG			XXXXh	1Ch
SPBRGH			XXXXh	) 00h

#### FIGURE 16-1: AUTOMATIC BAUD RATE CALCULATION

# 16.3 EUSART Asynchronous Mode

The Asynchronous mode of operation is selected by clearing the SYNC bit (TXSTA<4>). In this mode, the EUSART uses standard Non-Return-to-Zero (NRZ) format (one Start bit, eight or nine data bits and one Stop bit). The most common data format is 8 bits. An on-chip dedicated 8-bit/16-bit Baud Rate Generator can be used to derive standard baud rate frequencies from the oscillator.

The EUSART transmits and receives the LSb first. The EUSART's transmitter and receiver are functionally independent, but use the same data format and baud rate. The Baud Rate Generator produces a clock, either x16 or x64 of the bit shift rate, depending on the BRGH and BRG16 bits (TXSTA<2> and BAUDCTL<3>). Parity is not supported by the hardware, but can be implemented in software and stored as the 9th data bit.

Asynchronous mode is available in all low-power modes; it is available in Sleep mode only when autowake-up on Sync Break is enabled. When in PRI\_IDLE mode, no changes to the Baud Rate Generator values are required; however, other low-power mode clocks may operate at another frequency than the primary clock. Therefore, the Baud Rate Generator values may need to be adjusted.

When operating in Asynchronous mode, the EUSART module consists of the following important elements:

- Baud Rate Generator
- Sampling Circuit
- Asynchronous Transmitter
- Asynchronous Receiver
- Auto-Wake-up on Sync Break Character
- 12-bit Break Character Transmit
- Auto-Baud Rate Detection

# 16.3.1 EUSART ASYNCHRONOUS TRANSMITTER

The EUSART transmitter block diagram is shown in Figure 16-2. The heart of the transmitter is the Transmit (Serial) Shift Register (TSR). The shift register obtains its data from the Read/Write Transmit Buffer register, TXREG. The TXREG register is loaded with data in software. The TSR register is not loaded until the Stop bit has been transmitted from the previous load. As soon as the Stop bit is transmitted, the TSR is loaded with new data from the TXREG register (if available).

Once the TXREG register transfers the data to the TSR register (occurs in one TcY), the TXREG register is empty and flag bit, TXIF (PIR1<4>), is set. This interrupt can be enabled/disabled by setting/clearing enable bit, TXIE (PIE1<4>). Flag bit, TXIF, will be set, regardless of the state of enable bit, TXIE, and cannot be cleared in software. Flag bit, TXIF, is not cleared immediately upon loading the Transmit Buffer register, TXREG. TXIF becomes valid in the second instruction cycle following the load instruction. Polling TXIF immediately following a load of TXREG will return invalid results.

While flag bit, TXIF, indicates the status of the TXREG register, another bit, TRMT (TXSTA<1>), shows the status of the TSR register. Status bit, TRMT, is a readonly bit, which is set when the TSR register is empty. No interrupt logic is tied to this bit, so the user has to poll this bit in order to determine if the TSR register is empty.

**Note 1:** The TSR register is not mapped in data memory, so it is not available to the user.

**2:** Flag bit, TXIF, is set when enable bit, TXEN, is set.

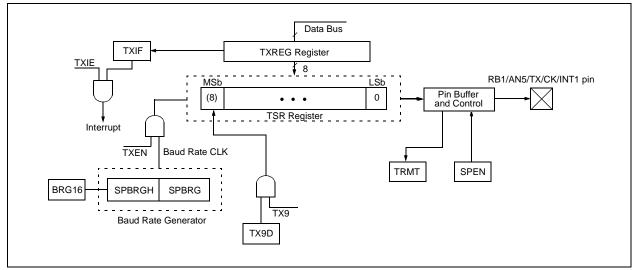

To set up an Asynchronous Transmission:

- 1. Initialize the SPBRGH:SPBRG registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing bit SYNC and setting bit SPEN.
- 3. If interrupts are desired, set enable bit TXIE.
- 4. If 9-bit transmission is desired, set transmit bit TX9. Can be used as address/data bit.

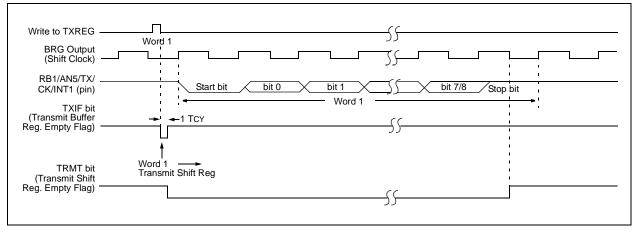

- 5. Enable the transmission by setting bit TXEN, which will also set bit TXIF.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
- 7. Load data to the TXREG register (starts transmission).

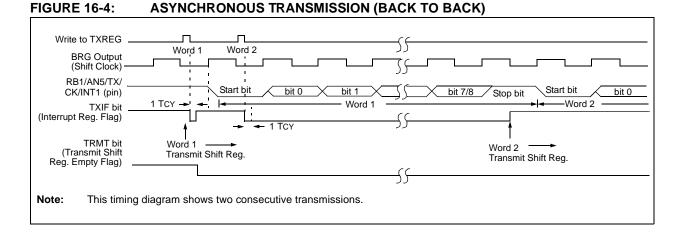

If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

Legend: x = unknown, - = unimplemented locations read as '0'. Shaded cells are not used for asynchronous transmission.

#### 16.3.2 EUSART ASYNCHRONOUS RECEIVER

The receiver block diagram is shown in Figure 16-5. The data is received on the RB4/AN6/RX/DT/KBI0 pin and drives the data recovery block. The data recovery block is actually a high-speed shifter, operating at x16 times the baud rate, whereas the main receive serial shifter operates at the bit rate or at Fosc. This mode would typically be used in RS-232 systems.

To set up an Asynchronous Reception:

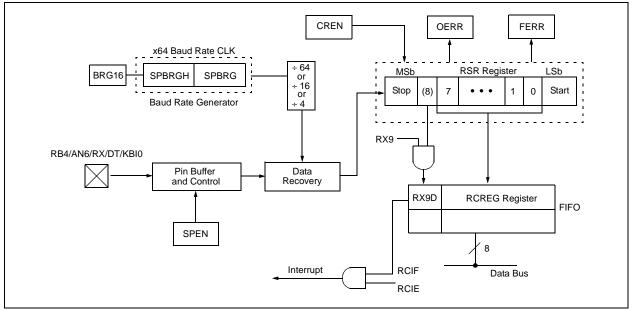

- 1. Initialize the SPBRGH:SPBRG registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing bit SYNC and setting bit SPEN.
- 3. If interrupts are desired, set enable bit RCIE.
- 4. If 9-bit reception is desired, set bit RX9.
- 5. Enable the reception by setting bit CREN.
- 6. Flag bit, RCIF, will be set when reception is complete and an interrupt will be generated if enable bit RCIE was set.
- 7. Read the RCSTA register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 8. Read the 8-bit received data by reading the RCREG register.
- 9. If any error occurred, clear the error by clearing enable bit CREN.
- 10. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

## 16.3.3 SETTING UP 9-BIT MODE WITH ADDRESS DETECT

This mode would typically be used in RS-485 systems. To set up an Asynchronous Reception with Address Detect Enable:

- 1. Initialize the SPBRGH:SPBRG registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing the SYNC bit and setting the SPEN bit.
- 3. If interrupts are required, set the RCEN bit and select the desired priority level with the RCIP bit.
- 4. Set the RX9 bit to enable 9-bit reception.
- 5. Set the ADDEN bit to enable address detect.
- 6. Enable reception by setting the CREN bit.
- 7. The RCIF bit will be set when reception is complete. The interrupt will be Acknowledged if the RCIE and GIE bits are set.
- 8. Read the RCSTA register to determine if any error occurred during reception, as well as read bit 9 of data (if applicable).
- 9. Read RCREG to determine if the device is being addressed.
- 10. If any error occurred, clear the CREN bit.
- 11. If the device has been addressed, clear the ADDEN bit to allow all received data into the receive buffer and interrupt the CPU.

#### FIGURE 16-5: EUSART RECEIVE BLOCK DIAGRAM

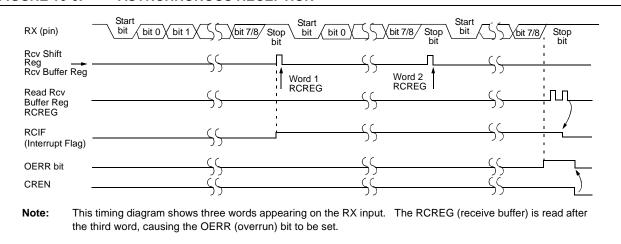

To set up an Asynchronous Transmission:

- Initialize the SPBRG register for the appropriate baud rate. If a high-speed baud rate is desired, set bit BRGH (see Section 16.2 "EUSART Baud Rate Generator (BRG)").
- 2. Enable the asynchronous serial port by clearing bit SYNC and setting bit SPEN.
- 3. If interrupts are desired, set enable bit TXIE.
- 4. If 9-bit transmission is desired, set transmit bit TX9. Can be used as address/data bit.

- 5. Enable the transmission by setting bit TXEN, which will also set bit TXIF.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
- 7. Load data to the TXREG register (starts transmission).

If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### TABLE 16-6: REGISTERS ASSOCIATED WITH ASYNCHRONOUS RECEPTION

#### FIGURE 16-6: ASYNCHRONOUS RECEPTION

#### 16.3.4 AUTO-WAKE-UP ON SYNC BREAK CHARACTER

During Sleep mode, all clocks to the EUSART are suspended. Because of this, the Baud Rate Generator is inactive and a proper byte reception cannot be performed. The auto-wake-up feature allows the controller to wake-up due to activity on the RX/DT line while the EUSART is operating in Asynchronous mode.

The auto-wake-up feature is enabled by setting the WUE bit (BAUDCTL<1>). Once set, the typical receive sequence on RX/DT is disabled and the EUSART remains in an Idle state, monitoring for a wake-up event independent of the CPU mode. A wake-up event consists of a high-to-low transition on the RX/DT line. (This coincides with the start of a Sync Break or a Wake-up Signal character for the LIN protocol.)

Following a wake-up event, the module generates an RCIF interrupt. The interrupt is generated synchronously to the Q clocks in normal operating modes (Figure 16-7) and asynchronously if the device is in Sleep mode (Figure 16-8). The interrupt condition is cleared by reading the RCREG register.

The WUE bit is automatically cleared once a low-to-high transition is observed on the RX line, following the wakeup event. At this point, the EUSART module is in Idle mode and returns to normal operation. This signals to the user that the Sync Break event is over.

### 16.3.4.1 Special Considerations Using Auto-Wake-up

Since auto-wake-up functions by sensing rising edge transitions on RX/DT, information with any state changes before the Stop bit may signal a false end-of-character

and cause data or framing errors. To work properly, therefore, the initial character in the transmission must be all '0's. This can be 00h (8 bytes) for standard RS-232 devices, or 000h (12 bits) for LIN bus.

Oscillator start-up time must also be considered, especially in applications using oscillators with longer start-up intervals (i.e., LP, XT or HS/PLL mode). The Sync Break (or Wake-up Signal) character must be of sufficient length and be followed by a sufficient period, to allow enough time for the selected oscillator to start and provide proper initialization of the EUSART.

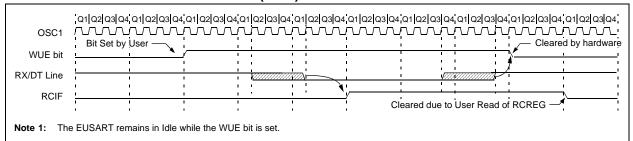

# 16.3.4.2 Special Considerations Using the WUE Bit

The timing of WUE and RCIF events may cause some confusion when it comes to determining the validity of received data. As noted, setting the WUE bit places the EUSART in an Idle mode. The wake-up event causes a receive interrupt by setting the RCIF bit. The WUE bit is cleared after this when a rising edge is seen on RX/ DT. The interrupt condition is then cleared by reading the RCREG register. Ordinarily, the data in RCREG will be dummy data and should be discarded.

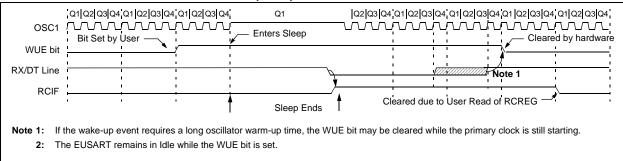

The fact that the WUE bit has been cleared (or is still set) and the RCIF flag is set should not be used as an indicator of the integrity of the data in RCREG. Users should consider implementing a parallel method in firmware to verify received data integrity.

To assure that no actual data is lost, check the RCIDL bit to verify that a receive operation is not in process. If a receive operation is not occurring, the WUE bit may then be set just prior to entering the Sleep mode.

#### FIGURE 16-7: AUTO-WAKE-UP BIT (WUE) TIMINGS DURING NORMAL OPERATION

#### FIGURE 16-8: AUTO-WAKE-UP BIT (WUE) TIMINGS DURING SLEEP

#### 16.3.5 BREAK CHARACTER SEQUENCE

The Enhanced USART module has the capability of sending the special Break character sequences that are required by the LIN bus standard. The Break character transmit consists of a Start bit, followed by twelve '0' bits and a Stop bit. The Frame Break character is sent whenever the SENDB and TXEN bits (TXSTA<3> and TXSTA<5>) are set while the Transmit Shift register is loaded with data. Note that the value of data written to TXREG will be ignored and all '0's will be transmitted.

The SENDB bit is automatically reset by hardware after the corresponding Stop bit is sent. This allows the user to preload the transmit FIFO with the next transmit byte following the Break character (typically, the Sync character in the LIN specification).

Note that the data value written to the TXREG for the Break character is ignored. The write simply serves the purpose of initiating the proper sequence.

The TRMT bit indicates when the transmit operation is active or Idle, just as it does during normal transmission. See Figure 16-9 for the timing of the Break character sequence.

#### 16.3.5.1 Transmitting A Break Signal

The Enhanced USART module has the capability of sending the Break signal that is required by the LIN bus standard. The Break signal consists of a Start bit, followed by twelve '0' bits and a Stop bit. The Break signal is sent whenever the SENDB (TXSTA<3>) and TXEN (TXSTA<5>) bits are set and TXREG is loaded with data. The data written to TXREG will be ignored and all '0's will be transmitted.

SENDB is automatically cleared by hardware when the Break signal has been sent. This allows the user to preload the transmit FIFO with the next transmit byte following the Break character (typically, the Sync character in the LIN specification).

The TRMT bit indicates when the transmit operation is active or Idle, just as it does during normal transmission.

To send a Break Signal:

- Configure the EUSART for asynchronous transmissions (steps 1-5). Initialize the SPBRG register for the appropriate baud rate. If a high-speed baud rate is desired, set bit BRGH (see Section 16.2 "EUSART Baud Rate Generator (BRG)").
- 2. Enable the asynchronous serial port by clearing bit SYNC and setting bit SPEN.
- 3. If interrupts are desired, set enable bit TXIE.

- 4. If 9-bit transmission is desired, set transmit bit TX9. Can be used as address/data bit.
- 5. Enable the transmission by setting bit TXEN, which will also set bit TXIF.
- 6. Set the SENDB bit.
- 7. Load a byte into TXREG. This triggers sending a Break signal. The Break signal is complete when TRMT is set. SENDB will also be cleared.

See Figure 16-9 for the timing of the Break signal sequence.

#### 16.3.6 RECEIVING A BREAK CHARACTER

The Enhanced USART module can receive a Break character in two ways.

The first method forces configuration of the baud rate at a frequency of 9/13 the typical speed. This allows for the Stop bit transition to be at the correct sampling location (12 bits for Break versus Start bit and 8 data bits for typical data).

The second method uses the auto-wake-up feature described in **Section 16.3.4 "Auto-Wake-up on Sync Break Character"**. By enabling this feature, the EUSART will sample the next two transitions on RX/DT, cause an RCIF interrupt and receive the next data byte followed by another interrupt.

Note that following a Break character, the user will typically want to enable the Auto-Baud Rate Detect feature. For both methods, the user can set the ABD bit before placing the EUSART in its Sleep mode.

#### 16.3.6.1 Transmitting a Break Sync

The following sequence will send a message frame header made up of a Break, followed by an auto-baud Sync byte. This sequence is typical of a LIN bus master.

- 1. Configure the EUSART for the desired mode.
- 2. Set the TXEN and SENDB bits to set up the Break character.
- 3. Load the TXREG with a dummy character to initiate transmission (the value is ignored).
- 4. Write '55h' to TXREG to load the Sync character into the transmit FIFO buffer.
- After the Break has been sent, the SENDB bit is reset by hardware. The Sync character now transmits in the preconfigured mode. When the TXREG becomes empty, as indicated by the TXIF, the next data byte can be written to TXREG.

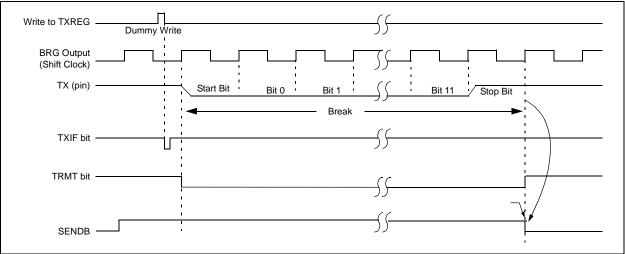

#### 16.3.6.2 Receiving a Break Sync

To receive a Break Sync:

- 1. Configure the EUSART for asynchronous transmit and receive. TXEN should remain clear. SPBRGH:SPBRG may be left as is.
- 2. Enable auto-wake-up. Set WUE.
- 3. Enable RXIF interrupts. Set RCIE, PEIE, GIE.
- 4. The controller may be placed in any power managed mode.
- 5. An RCIF will be generated at the beginning of the Break signal. When the interrupt is received, read RCREG to clear RCIF and discard. Allow the controller to return to PRI\_RUN mode.
- 6. Wait for the RX line to go high at the end of the Break signal. Wait for any of the following: WUE to clear automatically (poll), RB4/RX to go high (poll) or for RBIF to be set (poll or interrupt). If RBIF is used, check to be sure that RB4/RX is high before continuing.

- 7. Enable Auto-Baud Rate Detect. Set ABDEN.
- 8. Return from the interrupt. Allow the primary clock to start and stabilize (PRI\_RUN or PRI\_IDLE).
- 9. When the next RCIF interrupt occurs, the received baud rate has been measured. Read RCREG to clear RCIF and discard. Check SPBRGH:SPBRG for a valid value. The EUSART is ready for normal communications. Return from the interrupt. Allow the primary clock to run (PRI\_RUN or PRI\_IDLE).
- 10. Process subsequent RCIF interrupts normally as in asynchronous reception. TXEN should now be set if transmissions are needed. TXIF and TXIE may be set if transmit interrupts are desired. Remain in PRI\_RUN or PRI\_IDLE until communications are complete. Clear TXEN and return to step 2.

#### 16.4 EUSART Synchronous Master Mode

The Synchronous Master mode is entered by setting the CSRC bit (TXSTA<7>). In this mode, the data is transmitted in a half-duplex manner (i.e., transmission and reception do not occur at the same time). When transmitting data, the reception is inhibited and vice versa. Synchronous mode is entered by setting bit, SYNC (TXSTA<4>). In addition, enable bit, SPEN (RCSTA<7>), is set in order to configure the RB1/AN5/ TX/CK/INT1 and RB4/AN6/RX/DT/KBI0 I/O pins to CK (clock) and DT (data) lines, respectively.

The Master mode indicates that the processor transmits the master clock on the CK line. Clock polarity is selected with the SCKP bit (BAUDCTL<5>); setting SCKP sets the Idle state on CK as high, while clearing the bit sets the Idle state as low. This option is provided to support Microwire devices with this module.

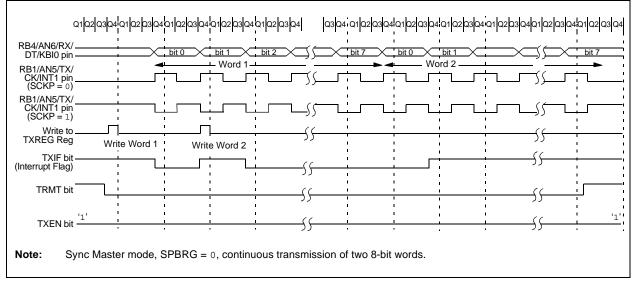

#### 16.4.1 EUSART SYNCHRONOUS MASTER TRANSMISSION

The EUSART transmitter block diagram is shown in Figure 16-2. The heart of the transmitter is the Transmit (Serial) Shift Register (TSR). The shift register obtains its data from the Read/Write Transmit Buffer register, TXREG. The TXREG register is loaded with data in software. The TSR register is not loaded until the last bit has been transmitted from the previous load. As soon as the last bit is transmitted, the TSR is loaded with new data from the TXREG (if available). Once the TXREG register transfers the data to the TSR register (occurs in one TCYCLE), the TXREG is empty and interrupt bit, TXIF (PIR1<4>), is set. The interrupt can be enabled/disabled by setting/clearing enable bit, TXIE (PIE1<4>). Flag bit, TXIF, will be set, regardless of the state of enable bit, TXIE and cannot be cleared in software. It will reset only when new data is loaded into the TXREG register.

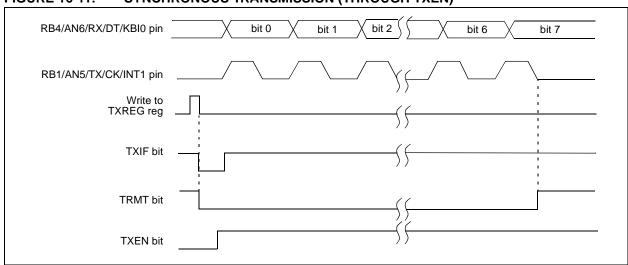

While flag bit, TXIF, indicates the status of the TXREG register, another bit, TRMT (TXSTA<1>), shows the status of the TSR register. TRMT is a read-only bit, which is set when the TSR is empty. No interrupt logic is tied to this bit, so the user has to poll this bit in order to determine if the TSR register is empty. The TSR is not mapped in data memory, so it is not available to the user.

To set up a Synchronous Master Transmission:

- 1. Initialize the SPBRGH:SPBRG registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the synchronous master serial port by setting bits SYNC, SPEN and CSRC.
- 3. If interrupts are desired, set enable bit TXIE.
- 4. If 9-bit transmission is desired, set bit TX9.
- 5. Enable the transmission by setting bit TXEN.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
- 7. Start transmission by loading data to the TXREG register.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### FIGURE 16-10: SYNCHRONOUS TRANSMISSION

#### FIGURE 16-11: SYNCHRONOUS TRANSMISSION (THROUGH TXEN)

TABLE 16-7: REGISTERS ASSOCIATED WITH SYNCHRONOUS MASTER TRANSMISSION

#### 16.4.2 EUSART SYNCHRONOUS MASTER RECEPTION

Once Synchronous mode is selected, reception is enabled by setting either the Single Receive Enable bit, SREN (RCSTA<5>), or the Continuous Receive Enable bit, CREN (RCSTA<4>). Data is sampled on the RB4/AN6/RX/DT/KBI0 pin on the falling edge of the clock.

If enable bit, SREN, is set, only a single word is received. If enable bit, CREN, is set, the reception is continuous until CREN is cleared. If both bits are set, then CREN takes precedence.

To set up a Synchronous Master Reception:

- 1. Initialize the SPBRGH:SPBRG registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the synchronous master serial port by setting bits SYNC, SPEN and CSRC.

- 3. Ensure bits CREN and SREN are clear.
- 4. If interrupts are desired, set enable bit RCIE.
- 5. If 9-bit reception is desired, set bit RX9.
- 6. If a single reception is required, set bit SREN. For continuous reception, set bit CREN.
- 7. Interrupt flag bit, RCIF, will be set when reception is complete and an interrupt will be generated if the enable bit, RCIE, was set.
- 8. Read the RCSTA register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 9. Read the 8-bit received data by reading the RCREG register.
- 10. If any error occurred, clear the error by clearing bit CREN.
- 11. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### TABLE 16-8: REGISTERS ASSOCIATED WITH SYNCHRONOUS MASTER RECEPTION

Legend: x = unknown, - = unimplemented, read as '0'. Shaded cells are not used for synchronous master reception.

#### 16.5 EUSART Synchronous Slave Mode

Synchronous Slave mode is entered by clearing bit, CSRC (TXSTA<7>). This mode differs from the Synchronous Master mode in that the shift clock is supplied externally at the RB1/AN5/TX/CK/INT1 pin (instead of being supplied internally in Master mode). This allows the device to transfer or receive data while in any low-power mode.

#### 16.5.1 EUSART SYNCHRONOUS SLAVE TRANSMIT

The operation of the Synchronous Master and Slave modes are identical, except in the case of the Sleep mode.

If two words are written to the TXREG and then the SLEEP instruction is executed, the following will occur:

- a) The first word will immediately transfer to the TSR register and transmit.
- b) The second word will remain in the TXREG register.
- c) Flag bit, TXIF, will not be set.
- d) When the first word has been shifted out of TSR, the TXREG register will transfer the second word to the TSR and flag bit, TXIF, will now be set.
- e) If enable bit, TXIE, is set, the interrupt will wake the chip from Sleep. If the global interrupt is enabled, the program will branch to the interrupt vector.

To set up a Synchronous Slave Transmission:

- Enable the synchronous slave serial port by setting bits SYNC and SPEN and clearing bit CSRC.
- 2. Clear bits CREN and SREN.
- 3. If interrupts are desired, set enable bit TXIE.
- 4. If 9-bit transmission is desired, set bit TX9.
- 5. Enable the transmission by setting enable bit TXEN.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
- 7. Start transmission by loading data to the TXREG register.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### TABLE 16-9: REGISTERS ASSOCIATED WITH SYNCHRONOUS SLAVE TRANSMISSION

**Legend:** x = unknown, - = unimplemented, read as '0'. Shaded cells are not used for synchronous slave transmission.

#### 16.5.2 EUSART SYNCHRONOUS SLAVE RECEPTION

The operation of the Synchronous Master and Slave modes is identical, except in the case of Sleep, or any Idle mode and bit SREN, which is a "don't care" in Slave mode.

If receive is enabled by setting the CREN bit prior to entering Sleep or any Idle mode, then a word may be received while in this low-power mode. Once the word is received, the RSR register will transfer the data to the RCREG register; if the RCIE enable bit is set, the interrupt generated will wake the chip from low-power mode. If the global interrupt is enabled, the program will branch to the interrupt vector. To set up a Synchronous Slave Reception:

- Enable the synchronous master serial port by setting bits SYNC and SPEN and clearing bit CSRC.
- 2. If interrupts are desired, set enable bit RCIE.
- 3. If 9-bit reception is desired, set bit RX9.
- 4. To enable reception, set enable bit CREN.
- 5. Flag bit, RCIF, will be set when reception is complete. An interrupt will be generated if enable bit, RCIE, was set.
- 6. Read the RCSTA register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 7. Read the 8-bit received data by reading the RCREG register.
- 8. If any error occurred, clear the error by clearing bit CREN.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

## PIC18F1220/1320

NOTES:

### 17.0 10-BIT ANALOG-TO-DIGITAL CONVERTER (A/D) MODULE

The Analog-to-Digital (A/D) converter module has seven inputs for the PIC18F1220/1320 devices. This module allows conversion of an analog input signal to a corresponding 10-bit digital number.

A new feature for the A/D converter is the addition of programmable acquisition time. This feature allows the user to select a new channel for conversion and to set the GO/DONE bit immediately. When the GO/DONE bit is set, the selected channel is sampled for the programmed acquisition time before a conversion is actually started. This removes the firmware overhead that may have been required to allow for an acquisition (sampling) period (see Register 17-3 and Section 17.3 "Selecting and Configuring Automatic Acquisition Time"). The module has five registers:

- A/D Result High Register (ADRESH)
- A/D Result Low Register (ADRESL)
- A/D Control Register 0 (ADCON0)
- A/D Control Register 1 (ADCON1)
- A/D Control Register 2 (ADCON2)

The ADCON0 register, shown in Register 17-1, controls the operation of the A/D module. The ADCON1 register, shown in Register 17-2, configures the functions of the port pins. The ADCON2 register, shown in Register 17-3, configures the A/D clock source, programmed acquisition time and justification.

The analog reference voltage is software selectable to either the device's positive and negative supply voltage (AVDD and AVSS), or the voltage level on the RA3/AN3/VREF+ and RA2/AN2/VREF- pins.

The A/D converter has a unique feature of being able to operate while the device is in Sleep mode. To operate in Sleep, the A/D conversion clock must be derived from the A/D's internal RC oscillator.

The output of the sample and hold is the input into the converter, which generates the result via successive approximation.

#### FIGURE 17-1: A/D BLOCK DIAGRAM

A device Reset forces all registers to their Reset state. This forces the A/D module to be turned off and any conversion in progress is aborted.

Each port pin associated with the A/D converter can be configured as an analog input, or as a digital I/O. The ADRESH and ADRESL registers contain the result of the A/D conversion. When the A/D conversion is complete, the result is loaded into the ADRESH/ADRESL registers, the GO/DONE bit (ADCON0 register) is cleared and A/D Interrupt Flag bit, ADIF, is set. The block diagram of the A/D module is shown in Figure 17-1. The value in the ADRESH/ADRESL registers is not modified for a Power-on Reset. The ADRESH/ADRESL registers will contain unknown data after a Power-on Reset.

After the A/D module has been configured as desired, the selected channel must be acquired before the conversion is started. The analog input channels must have their corresponding TRIS bits selected as an input. To determine acquisition time, see **Section 17.1 "A/D Acquisition Requirements"**. After this acquisition time has elapsed, the A/D conversion can be started. An acquisition time <u>can be</u> programmed to occur between setting the GO/DONE bit and the actual start of the conversion. To do an A/D Conversion:

- 1. Configure the A/D module:
  - Configure analog pins, voltage reference and digital I/O (ADCON1)
  - Select A/D input channel (ADCON0)
  - Select A/D acquisition time (ADCON2)
  - Select A/D conversion clock (ADCON2)
  - Turn on A/D module (ADCON0)
- 2. Configure A/D interrupt (if desired):
  - Clear ADIF bit
  - Set ADIE bit
  - Set GIE bit
- 3. Wait the required acquisition time (if required).
- 4. Start conversion:
  - Set GO/DONE bit (ADCON0 register)
- 5. Wait for A/D conversion to complete, by either:
  - Polling for the GO/DONE bit to be cleared
    OR
  - Waiting for the A/D interrupt
- 6. Read A/D Result registers (ADRESH:ADRESL); clear bit, ADIF, if required.
- 7. For the next conversion, go to step 1 or step 2, as required. The A/D conversion time per bit is defined as TAD. A minimum wait of 2 TAD is required before the next acquisition starts.

**FIGURE 17-2:** ANALOG INPUT MODEL VDD Sampling Switch VT = 0.6VΛ ANx Ric ≤ 1k SS Rss -\\\\ CPIN ILEAKAGE CHOLD = 120 pF VT = 0.6V 5 pF ± 500 nA Vss Legend: CPIN = input capacitance Vт = threshold voltage 6V 5V ILEAKAGE = leakage current at the pin due to Vdd 4V various junctions ЗV RIC = interconnect resistance 2V SS = sampling switch CHOLD = sample/hold capacitance (from DAC) + + + + +Rss = sampling switch resistance 5 6 7 8 9 10 11 Sampling Switch (kΩ)

#### 17.1 A/D Acquisition Requirements

For the A/D converter to meet its specified accuracy, the charge holding capacitor (CHOLD) must be allowed to fully charge to the input channel voltage level. The analog input model is shown in Figure 17-2. The source impedance (Rs) and the internal sampling switch (Rss) impedance directly affect the time required to charge the capacitor CHOLD. The sampling switch (Rss) impedance varies over the device voltage (VDD). The source impedance affects the offset voltage at the analog input (due to pin leakage current). The maximum recommended impedance for analog sources is 2.5 k $\Omega$ . After the analog input channel is selected (changed), the channel must be sampled for at least the minimum acquisition time before starting a conversion.

Note:	When	the	conversion	is	started,	the		
	holding capacitor is disconnected from the							
	input p	in.						

To calculate the minimum acquisition time, Equation 17-1 may be used. This equation assumes that 1/2 LSb error is used (1024 steps for the A/D). The 1/2 LSb error is the maximum error allowed for the A/D to meet its specified resolution. Example 17-1 shows the calculation of the minimum required acquisition time, TACQ. This calculation is based on the following application system assumptions:

CHOLD	=	120 pF
Rs	=	2.5 kΩ
Conversion Error	$\leq$	1/2 LSb
Vdd	=	$5V  ightarrow Rss = 7 \ k\Omega$
Temperature	=	50°C (system max.)
VHOLD	=	0V @ time = 0

#### 17.2 A/D VREF+ and VREF- References

If external voltage references are used instead of the internal AVDD and AVss sources, the source impedance of the VREF+ and VREF- voltage sources must be considered. During acquisition, currents supplied by these sources are insignificant. However, during conversion, the A/D module sinks and sources current through the reference sources.

In order to maintain the A/D accuracy, the voltage reference source impedances should be kept low to reduce voltage changes. These voltage changes occur as reference currents flow through the reference source impedance. The maximum recommended impedance of the VREF+ and VREF- external reference voltage sources is  $250\Omega$ .

#### EQUATION 17-1: ACQUISITION TIME

- TACQ = Amplifier Settling Time + Holding Capacitor Charging Time + Temperature Coefficient
  - = TAMP + TC + TCOFF

#### EQUATION 17-2: A/D MINIMUM CHARGING TIME

- VHOLD =  $(\Delta VREF (\Delta VREF/2048)) \cdot (1 e^{(-TC/CHOLD(RIC + RSS + RS))})$
- or TC =  $-(CHOLD)(RIC + RSS + RS) \ln(1/2048)$

#### EXAMPLE 17-1: CALCULATING THE MINIMUM REQUIRED ACQUISITION TIME

TACQ =	TAMP + TC + TCOFF
TAMP =	5 µs
TCOFF =	(Temp – 25°C)(0.05 μs/°C)
	(50°C – 25°C)(0.05 µs/°C)
	1.25 μs
Temperatu	are coefficient is only required for temperatures > 25°C. Below 25°C, TCOFF = 0 $\mu$ s.
TC =	-(Chold)(Ric + Rss + Rs) $\ln(1/2047) \mu s$
	-(120 pF) (1 k $\Omega$ + 7 k $\Omega$ + 2.5 k $\Omega$ ) ln(0.0004883) $\mu$ s
	9.61 µs
TACQ =	$5 \mu s + 1.25 \mu s + 9.61 \mu s$
	12.86 µs

#### 17.3 Selecting and Configuring Automatic Acquisition Time

The ADCON2 register allows the user to select an acquisition time that occurs each time the GO/DONE bit is set.

When the GO/DONE bit is set, sampling is stopped and a conversion begins. The user is responsible for ensuring the required acquisition time has passed between selecting the desired input channel and setting the GO/DONE bit. This occurs when the ACQT2:ACQT0 bits (ADCON2<5:3>) remain in their Reset state ('000') and is compatible with devices that do not offer programmable acquisition times.

If desired, the ACQT bits can be set to select a programmable acquisition time for the A/D module. When the GO/DONE bit is set, the A/D module continues to sample the input for the selected acquisition time, then automatically begins a conversion. Since the acquisition time is programmed, there may be no need to wait for an acquisition time between selecting a channel and setting the GO/DONE bit.

In either case, when the conversion is completed, the GO/DONE bit is cleared, the ADIF flag is set and the A/D begins sampling the currently selected channel again. If an acquisition time is programmed, there is nothing to indicate if the acquisition time has ended or if the conversion has begun.

#### 17.4 Selecting the A/D Conversion Clock

The A/D conversion time per bit is defined as TAD. The A/D conversion requires 11 TAD per 10-bit conversion. The source of the A/D conversion clock is software selectable. There are seven possible options for TAD:

- 2 Tosc
- 4 Tosc
- 8 Tosc
- 16 Tosc
- 32 Tosc
- 64 Tosc
- Internal RC oscillator

For correct A/D conversions, the A/D conversion clock (TAD) must be as short as possible, but greater than the minimum TAD (approximately 2  $\mu$ s, see parameter 130 for more information).

Table 17-1 shows the resultant TAD times derived from the device operating frequencies and the A/D clock source selected.

AD Clock S	ource (TAD)	Maximum De	vice Frequency
Operation	ADCS2:ADCS0	PIC18F1220/1320	PIC18LF1220/1320 <sup>(4)</sup>
2 Tosc	000	1.25 MHz	666 kHz
4 Tosc	100	2.50 MHz	1.33 MHz
8 Tosc	001	5.00 MHz	2.66 MHz
16 Tosc	101	10.0 MHz	5.33 MHz
32 Tosc	010	20.0 MHz	10.65 MHz
64 Tosc	110	40.0 MHz	21.33 MHz
RC <sup>(3)</sup>	x11	1.00 MHz <sup>(1)</sup>	1.00 MHz <sup>(2)</sup>

#### TABLE 17-1: TAD vs. DEVICE OPERATING FREQUENCIES

**Note 1:** The RC source has a typical TAD time of 4  $\mu$ s.

**2:** The RC source has a typical TAD time of 6 μs.

**3:** For device frequencies above 1 MHz, the device must be in Sleep for the entire conversion or the A/D accuracy may be out of specification.

4: Low-power devices only.

#### 17.5 Operation in Low-Power Modes

The selection of the automatic acquisition time and the A/D conversion clock is determined, in part, by the low-power mode clock source and frequency while in a low-power mode.

If the A/D is expected to operate while the device is in a low-power mode, the ACQT2:ACQT0 and ADCS2:ADCS0 bits in ADCON2 should be updated in accordance with the low-power mode clock that will be used. After the low-power mode is entered (either of the Run modes), an A/D acquisition or conversion may be started. Once an acquisition or conversion is started, the device should continue to be clocked by the same low-power mode clock source until the conversion has been completed. If desired, the device may be placed into the corresponding low-power (ANY)\_IDLE mode during the conversion.

If the low-power mode clock frequency is less than 1 MHz, the A/D RC clock source should be selected.

Operation in the Low-Power Sleep mode requires the A/D RC clock to be selected. If bits, ACQT2:ACQT0, are set to '000' and a conversion is started, the conversion will be delayed one instruction cycle to allow execution of the SLEEP instruction and entry to Low-Power Sleep mode. The IDLEN and SCS bits in the OSCCON register must have already been cleared prior to starting the conversion.

#### 17.6 Configuring Analog Port Pins

The ADCON1, TRISA and TRISB registers all configure the A/D port pins. The port pins needed as analog inputs must have their corresponding TRIS bits set (input). If the TRIS bit is cleared (output), the digital output level (VOH or VOL) will be converted.

The A/D operation is independent of the state of the CHS2:CHS0 bits and the TRIS bits.

- Note 1: When reading the Port register, all pins configured as analog input channels will read as cleared (a low level). Pins configured as digital inputs will convert an analog input. Analog levels on a digitally configured input will be accurately converted.
  - 2: Analog levels on any pin defined as a digital input may cause the digital input buffer to consume current out of the device's specification limits.

#### 17.7 A/D Conversions

Figure 17-3 shows the operation of the A/D converter after the GO bit has been set and the ACQT2:ACQT0 bits are cleared. A conversion is started after the following instruction to allow entry into Low-Power Sleep mode before the conversion begins.

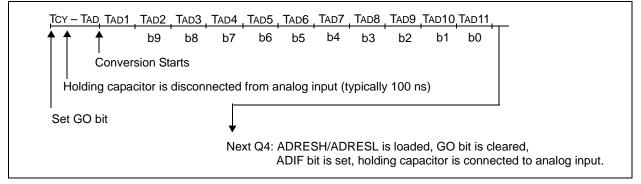

Figure 17-4 shows the operation of the A/D converter after the GO bit has been set and the ACQT2:ACQT0 bits are set to '010' and selecting a 4 TAD acquisition time before the conversion starts.

Clearing the GO/DONE bit during a conversion will abort the current conversion. The A/D Result register pair will NOT be updated with the partially completed A/D conversion sample. This means the ADRESH:ADRESL registers will continue to contain the value of the last completed conversion (or the last value written to the ADRESH:ADRESL registers).

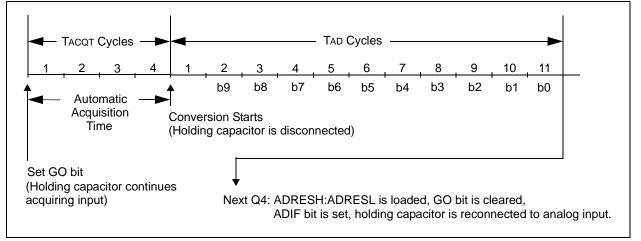

After the A/D conversion is completed or aborted, a 2 TAD wait is required before the next acquisition can be started. After this wait, acquisition on the selected channel is automatically started.

**Note:** The GO/DONE bit should **NOT** be set in the same instruction that turns on the A/D.

#### FIGURE 17-3: A/D CONVERSION TAD CYCLES (Acqt<2:0> = 000, Tacq = 0)

#### FIGURE 17-4: A/D CONVERSION TAD CYCLES (Acqt<2:0> = 010, Tacq = 4 TAD)

#### 17.8 Use of the CCP1 Trigger

An A/D conversion can be started by the "special event trigger" of the CCP1 module. This requires that the CCP1M3:CCP1M0 bits (CCP1CON<3:0>) be programmed as '1011' and that the A/D module is enabled (ADON bit is set). When the trigger occurs, the GO/DONE bit will be set, starting the A/D acquisition and conversion and the Timer1 (or Timer3) counter will be reset to zero. Timer1 (or Timer3) is reset to automatically repeat the A/D acquisition period with minimal

software overhead (moving ADRESH/ADRESL to the desired location). The appropriate analog input channel must be selected and the minimum acquisition period is either timed by the user, or an appropriate TACQ time selected before the "special event trigger" sets the GO/DONE bit (starts a conversion).

If the A/D module is not enabled (ADON is cleared), the "special event trigger" will be ignored by the A/D module, but will still reset the Timer1 (or Timer3) counter.

TABLE 17-2:SUMMARY OF A/D REGISTERS

Note 1: RA5 port bit is available only as an input pin when the MCLRE bit in the configuration register is '0'.

2: RA6 and TRISA6 are available only when the primary oscillator mode selection offers RA6 as a port pin; otherwise, RA6 always reads '0', TRISA6 always reads '1' and writes to both are ignored (see CONFIG1H<3:0>).

3: RA7 and TRISA7 are available only when the internal RC oscillator is configured as the primary oscillator in CONFIG1H<3:0>; otherwise, RA7 always reads '0', TRISA7 always reads '1' and writes to both are ignored.

### 18.0 LOW-VOLTAGE DETECT

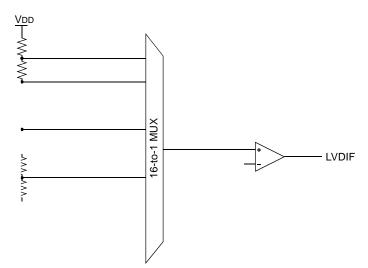

In many applications, the ability to determine if the device voltage (VDD) is below a specified voltage level is a desirable feature. A window of operation for the application can be created, where the application software can do "housekeeping tasks", before the device voltage exits the valid operating range. This can be done using the Low-Voltage Detect module.

This module is a software programmable circuitry, where a device voltage trip point can be specified. When the voltage of the device becomes lower then the specified point, an interrupt flag is set. If the interrupt is enabled, the program execution will branch to the interrupt vector address and the software can then respond to that interrupt source.

The Low-Voltage Detect circuitry is completely under software control. This allows the circuitry to be turned off by the software, which minimizes the current consumption for the device. Figure 18-1 shows a possible application voltage curve (typically for batteries). Over time, the device voltage decreases. When the device voltage equals voltage VA,

#### 18.2 Operation

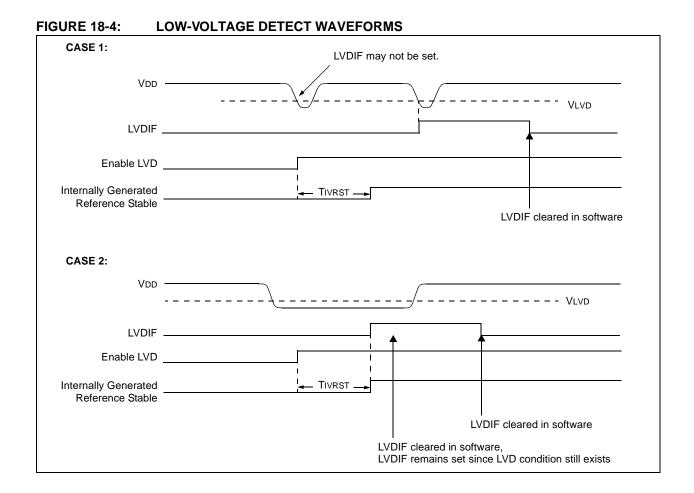

Depending on the power source for the device voltage, the voltage normally decreases relatively slowly. This means that the LVD module does not need to be constantly operating. To decrease the current requirements, the LVD circuitry only needs to be enabled for short periods, where the voltage is checked. After doing the check, the LVD module may be disabled.

Each time that the LVD module is enabled, the circuitry requires some time to stabilize. After the circuitry has stabilized, all status flags may be cleared. The module will then indicate the proper state of the system.

The following steps are needed to set up the LVD module:

- Write the value to the LVDL3:LVDL0 bits (LVDCON register), which selects the desired LVD trip point.
- 2. Ensure that LVD interrupts are disabled (the LVDIE bit is cleared or the GIE bit is cleared).
- 3. Enable the LVD module (set the LVDEN bit in the LVDCON register).
- 4. Wait for the LVD module to stabilize (the IRVST bit to become set).
- 5. Clear the LVD interrupt flag, which may have falsely become set, until the LVD module has stabilized (clear the LVDIF bit).
- 6. Enable the LVD interrupt (set the LVDIE and the GIE bits).

Figure 18-4 shows typical waveforms that the LVD module may be used to detect.

#### 18.2.1 REFERENCE VOLTAGE SET POINT

The internal reference voltage of the LVD module may be used by other internal circuitry (the programmable Brown-out Reset). If these circuits are disabled (lower current consumption), the reference voltage circuit requires a time to become stable before a low-voltage condition can be reliably detected. This time is invariant of system clock speed. This start-up time is specified in electrical specification parameter 36. The low-voltage interrupt flag will not be enabled until a stable reference voltage is reached. Refer to the waveform in Figure 18-4.

#### 18.2.2 CURRENT CONSUMPTION

When the module is enabled, the LVD comparator and voltage divider are enabled and will consume static current. The voltage divider can be tapped from multiple places in the resistor array. Total current consumption, when enabled, is specified in electrical specification parameter D022B.

#### 18.3 Operation During Sleep

When enabled, the LVD circuitry continues to operate during Sleep. If the device voltage crosses the trip point, the LVDIF bit will be set and the device will wakeup from Sleep. Device execution will continue from the interrupt vector address if interrupts have been globally enabled.

#### 18.4 Effects of a Reset

A device Reset forces all registers to their Reset state. This forces the LVD module to be turned off.

## PIC18F1220/1320

NOTES:

### 19.0 SPECIAL FEATURES OF THE CPU

PIC18F1220/1320 devices include several features intended to maximize system reliability, minimize cost through elimination of external components and offer code protection. These are:

- Oscillator Selection
- Resets:
  - Power-on Reset (POR)
  - Power-up Timer (PWRT)
  - Oscillator Start-up Timer (OST)
  - Brown-out Reset (BOR)
- Interrupts
- Watchdog Timer (WDT)
- Fail-Safe Clock Monitor
- Two-Speed Start-up
- Code Protection
- ID Locations
- In-Circuit Serial Programming

Several oscillator options are available to allow the part to fit the application. The RC oscillator option saves system cost, while the LP crystal option saves power. These are discussed in detail in **Section 2.0 "Oscillator Configurations"**.

A complete discussion of device Resets and interrupts is available in previous sections of this data sheet.

In addition to their Power-up and Oscillator Start-up Timers provided for Resets, PIC18F1220/1320 devices have a Watchdog Timer, which is either permanently enabled via the configuration bits, or software controlled (if configured as disabled). The inclusion of an internal RC oscillator also provides the additional benefits of a Fail-Safe Clock Monitor (FSCM) and Two-Speed Start-up. FSCM provides for background monitoring of the peripheral clock and automatic switchover in the event of its failure. Two-Speed Start-up enables code to be executed almost immediately on start-up, while the primary clock source completes its start-up delays.

All of these features are enabled and configured by setting the appropriate configuration register bits.

#### **19.1 Configuration Bits**

The configuration bits can be programmed (read as '0'), or left unprogrammed (read as '1'), to select various device configurations. These bits are mapped starting at program memory location 300000h.

The user will note that address 300000h is beyond the user program memory space. In fact, it belongs to the configuration memory space (300000h-3FFFFh), which can only be accessed using table reads and table writes.

Programming the configuration registers is done in a manner similar to programming the Flash memory. The EECON1 register WR bit starts a self-timed write to the configuration register. In normal operation mode, a TBLWT instruction, with the TBLPTR pointing to the configuration register, sets up the address and the data for the configuration register write. Setting the WR bit starts a long write to the configuration register. The configuration registers are written a byte at a time. To write or erase a configuration cell, a TBLWT instruction can write a '1' or a '0' into the cell. For additional details on Flash programming, refer to Section 6.5 "Writing to Flash Program Memory".

Note: The Timer1 oscillator shares the T1OSI and T1OSO pins with the PGD and PGC pins used for programming and debugging.
 When using the Timer1 oscillator, In-Circuit Serial Programming (ICSP) may not function correctly (high voltage or low voltage), or the In-Circuit Debugger (ICD) may not communicate with the controller. As a result of using either ICSP or ICD, the Timer1 crystal may be damaged.
 If ICSP or ICD operations are required, the crystal should be disconnected from the circuit (disconnect either lead) or installed after programming. The oscillator loading capacitors may remain in-circuit during ICSP or ICD operation.

### 19.2 Watchdog Timer (WDT)

For PIC18F1220/1320 devices, the WDT is driven by the INTRC source. When the WDT is enabled, the clock source is also enabled. The nominal WDT period is 4 ms and has the same stability as the INTRC oscillator.

The 4 ms period of the WDT is multiplied by a 16-bit postscaler. Any output of the WDT postscaler is selected by a multiplexer, controlled by bits in Configuration Register 2H. Available periods range from 4 ms to 131.072 seconds (2.18 minutes). The WDT and postscaler are cleared when any of the following events occur: execute a SLEEP or CLRWDT instruction, the IRCF bits (OSCCON<6:4>) are changed or a clock failure has occurred.

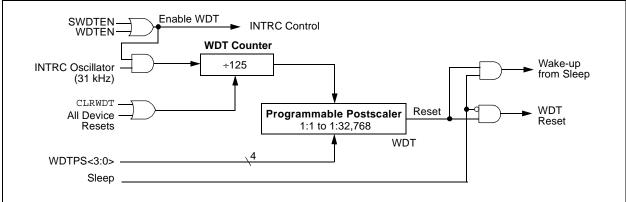

Adjustments to the internal oscillator clock period using the OSCTUNE register also affect the period of the WDT by the same factor. For example, if the INTRC period is increased by 3%, then the WDT period is increased by 3%.

- Note 1: The CLRWDT and SLEEP instructions clear the WDT and postscaler counts when executed.
  - 2: Changing the setting of the IRCF bits (OSCCON<6:4>) clears the WDT and postscaler counts.
  - **3:** When a CLRWDT instruction is executed the postscaler count will be cleared.

#### 19.2.1 CONTROL REGISTER

Register 19-14 shows the WDTCON register. This is a readable and writable register, which contains a control bit that allows software to override the WDT enable configuration bit, only if the configuration bit has disabled the WDT.

TABLE 19-2: SUMMARY OF WATCHDOG TIMER REGISTERS

Legend: Shaded cells are not used by the Watchdog Timer.

### 19.3 Two-Speed Start-up

The Two-Speed Start-up feature helps to minimize the latency period from oscillator start-up to code execution by allowing the microcontroller to use the INTRC oscillator as a clock source until the primary clock source is available. It is enabled by setting the IESO bit in Configuration Register 1H (CONFIG1H<7>).

Two-Speed Start-up is available only if the primary oscillator mode is LP, XT, HS or HSPLL (crystal-based modes). Other sources do not require an OST start-up delay; for these, Two-Speed Start-up is disabled.

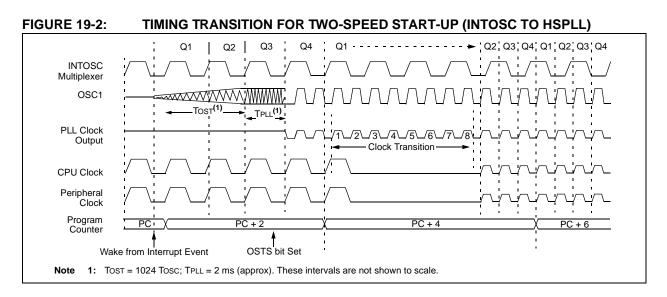

When enabled, Resets and wake-ups from Sleep mode cause the device to configure itself to run from the internal oscillator block as the clock source, following the time-out of the Power-up Timer after a Power-on Reset is enabled. This allows almost immediate code execution while the primary oscillator starts and the OST is running. Once the OST times out, the device automatically switches to PRI\_RUN mode.

Because the OSCCON register is cleared on Reset events, the INTOSC (or postscaler) clock source is not initially available after a Reset event; the INTRC clock is used directly at its base frequency. To use a higher clock speed on wake-up, the INTOSC or postscaler clock sources can be selected to provide a higher clock speed by setting bits, IFRC2:IFRC0, immediately after Reset. For wake-ups from Sleep, the INTOSC or postscaler clock sources can be selected by setting IFRC2:IFRC0 prior to entering Sleep mode. In all other power managed modes, Two-Speed Start-up is not used. The device will be clocked by the currently selected clock source until the primary clock source becomes available. The setting of the IESO bit is ignored.

## 19.3.1 SPECIAL CONSIDERATIONS FOR USING TWO-SPEED START-UP

While using the INTRC oscillator in Two-Speed Startup, the device still obeys the normal command sequences for entering power managed modes, including serial SLEEP instructions (refer to **Section 3.1.3 "Multiple Sleep Commands"**). In practice, this means that user code can change the SCS1:SCS0 bit settings and issue SLEEP commands before the OST times out. This would allow an application to briefly wake-up, perform routine "housekeeping" tasks and return to Sleep before the device starts to operate from the primary oscillator.

User code can also check if the primary clock source is currently providing the system clocking by checking the status of the OSTS bit (OSCCON<3>). If the bit is set, the primary oscillator is providing the system clock. Otherwise, the internal oscillator block is providing the clock during wake-up from Reset or Sleep mode.

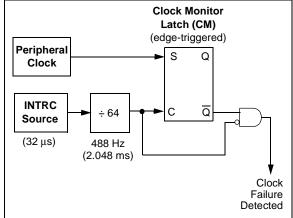

### 19.4 Fail-Safe Clock Monitor

The Fail-Safe Clock Monitor (FSCM) allows the microcontroller to continue operation, in the event of an external oscillator failure, by automatically switching the system clock to the internal oscillator block. The FSCM function is enabled by setting the Fail-Safe Clock Monitor Enable bit, FSCM (CONFIG1H<6>).

When FSCM is enabled, the INTRC oscillator runs at all times to monitor clocks to peripherals and provide an instant backup clock in the event of a clock failure. Clock monitoring (shown in Figure 19-3) is accomplished by creating a sample clock signal, which is the INTRC output divided by 64. This allows ample time between FSCM sample clocks for a peripheral clock edge to occur. The peripheral system clock and the sample clock are presented as inputs to the Clock Monitor latch (CM). The CM is set on the falling edge of the system clock source, but cleared on the rising edge of the sample clock.

Clock failure is tested for on the falling edge of the sample clock. If a sample clock falling edge occurs while CM is still set, a clock failure has been detected (Figure 19-4). This causes the following:

- the FSCM generates an oscillator fail interrupt by setting bit, OSCFIF (PIR2<7>);
- the system clock source is switched to the internal oscillator block (OSCCON is not updated to show the current clock source – this is the Fail-Safe condition); and
- the WDT is reset.

Since the postscaler frequency from the internal oscillator block may not be sufficiently stable, it may be desirable to select another clock configuration and enter an alternate power managed mode (see Section 19.3.1 "Special Considerations for Using Two-Speed Start-up" and Section 3.1.3 "Multiple Sleep Commands" for more details). This can be done to attempt a partial recovery, or execute a controlled shutdown.

To use a higher clock speed on wake-up, the INTOSC or postscaler clock sources can be selected to provide a higher clock speed by setting bits, IFRC2:IFRC0, immediately after Reset. For wake-ups from Sleep, the INTOSC or postscaler clock sources can be selected by setting IFRC2:IFRC0 prior to entering Sleep mode.

Adjustments to the internal oscillator block, using the OSCTUNE register, also affect the period of the FSCM by the same factor. This can usually be neglected, as the clock frequency being monitored is generally much higher than the sample clock frequency.

The FSCM will detect failures of the primary or secondary clock sources only. If the internal oscillator block fails, no failure would be detected, nor would any action be possible.

#### 19.4.1 FSCM AND THE WATCHDOG TIMER

Both the FSCM and the WDT are clocked by the INTRC oscillator. Since the WDT operates with a separate divider and counter, disabling the WDT has no effect on the operation of the INTRC oscillator when the FSCM is enabled.

As already noted, the clock source is switched to the INTOSC clock when a clock failure is detected. Depending on the frequency selected by the IRCF2:IRCF0 bits, this may mean a substantial change in the speed of code execution. If the WDT is enabled with a small prescale value, a decrease in clock speed allows a WDT time-out to occur and a subsequent device Reset. For this reason, Fail-Safe Clock events also reset the WDT and postscaler, allowing it to start timing from when execution speed was changed and decreasing the likelihood of an erroneous time-out.

### 19.4.2 EXITING FAIL-SAFE OPERATION

The Fail-Safe condition is terminated by either a device Reset, or by entering a power managed mode. On Reset, the controller starts the primary clock source specified in Configuration Register 1H (with any required start-up delays that are required for the oscillator mode, such as OST or PLL timer). The INTOSC multiplexer provides the system clock until the primary clock source becomes ready (similar to a Two-Speed Start-up). The clock system source is then switched to the primary clock (indicated by the OSTS bit in the OSCCON register becoming set). The Fail-Safe Clock Monitor then resumes monitoring the peripheral clock.

The primary clock source may never become ready during start-up. In this case, operation is clocked by the INTOSC multiplexer. The OSCCON register will remain in its Reset state until a power managed mode is entered.

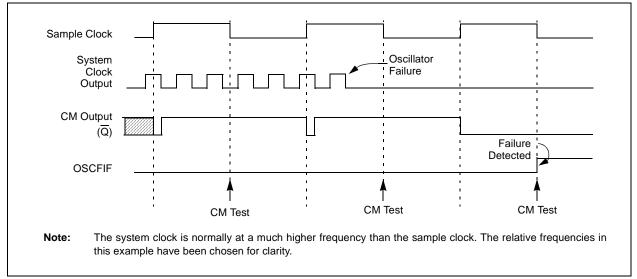

Entering a power managed mode by loading the OSCCON register and executing a SLEEP instruction will clear the Fail-Safe condition. When the Fail-Safe condition is cleared, the clock monitor will resume monitoring the peripheral clock.

#### 19.4.3 FSCM INTERRUPTS IN POWER MANAGED MODES

As previously mentioned, entering a power managed mode clears the Fail-Safe condition. By entering a power managed mode, the clock multiplexer selects the clock source selected by the OSCCON register. Fail-Safe monitoring of the power managed clock source resumes in the power managed mode.

If an oscillator failure occurs during power managed operation, the subsequent events depend on whether or not the oscillator failure interrupt is enabled. If enabled (OSCFIF = 1), code execution will be clocked by the INTOSC multiplexer. An automatic transition back to the failed clock source will not occur.

If the interrupt is disabled, the device will not exit the power managed mode on oscillator failure. Instead, the device will continue to operate as before, but clocked by the INTOSC multiplexer. While in Idle mode, subsequent interrupts will cause the CPU to begin executing instructions while being clocked by the INTOSC multiplexer. The device will not transition to a different clock source until the Fail-Safe condition is cleared.

#### FIGURE 19-4: FSCM TIMING DIAGRAM

### 19.4.4 POR OR WAKE FROM SLEEP

The FSCM is designed to detect oscillator failure at any point after the device has exited Power-on Reset (POR) or Low-Power Sleep mode. When the primary system clock is EC, RC or INTRC modes, monitoring can begin immediately following these events.

For oscillator modes involving a crystal or resonator (HS, HSPLL, LP or XT), the situation is somewhat different. Since the oscillator may require a start-up time considerably longer than the FCSM sample clock time, a false clock failure may be detected. To prevent this, the internal oscillator block is automatically configured as the system clock and functions until the primary clock is stable (the OST and PLL timers have timed out). This is identical to Two-Speed Start-up mode. Once the primary clock is stable, the INTRC returns to its role as the FSCM source Note: The same logic that prevents false oscillator failure interrupts on POR or wake from Sleep will also prevent the detection of the oscillator's failure to start at all following these events. This can be avoided by monitoring the OSTS bit and using a timing routine to determine if the oscillator is taking too long to start. Even so, no oscillator failure interrupt will be flagged.

As noted in Section 19.3.1 "Special Considerations for Using Two-Speed Start-up", it is also possible to select another clock configuration and enter an alternate power managed mode while waiting for the primary system clock to become stable. When the new powered managed mode is selected, the primary clock is disabled.

### 19.5 Program Verification and Code Protection

The overall structure of the code protection on the PIC18 Flash devices differs significantly from other PICmicro devices.

The user program memory is divided into three blocks. One of these is a boot block of 512 bytes. The remainder of the memory is divided into two blocks on binary boundaries. Each of the three blocks has three protection bits associated with them. They are:

- Code-Protect bit (CPn)
- Write-Protect bit (WRTn)
- External Block Table Read bit (EBTRn)

Figure 19-5 shows the program memory organization for 4 and 8-Kbyte devices and the specific code protection bit associated with each block. The actual locations of the bits are summarized in Table 19-3.

#### FIGURE 19-5: CODE-PROTECTED PROGRAM MEMORY FOR PIC18F1220/1320

#### 19.5.1 PROGRAM MEMORY CODE PROTECTION

The program memory may be read to, or written from, any location using the table read and table write instructions. The device ID may be read with table reads. The configuration registers may be read and written with the table read and table write instructions.

In normal execution mode, the CPn bits have no direct effect. CPn bits inhibit external reads and writes. A block of user memory may be protected from table writes if the WRTn configuration bit is '0'. The EBTRn bits control table reads. For a block of user memory with the EBTRn bit set to '0', a table read instruction that executes from within that block is allowed to read. A table read instruction that executes from a location outside of that block is not allowed to read and will result in reading '0's. Figures 19-6 through 19-8 illustrate table write and table read protection. Note: Code protection bits may only be written to a '0' from a '1' state. It is not possible to write a '1' to a bit in the '0' state. Code protection bits are only set to '1' by a full Chip Erase or Block Erase function. The full Chip Erase and Block Erase functions can only be initiated via ICSP or an external programmer.

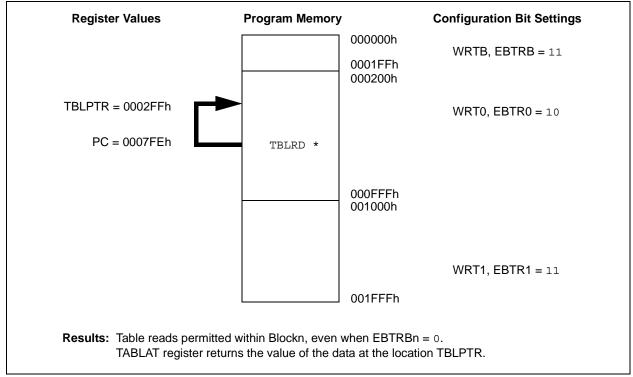

#### FIGURE 19-6: TABLE WRITE (WRTn) DISALLOWED: PIC18F1320

#### FIGURE 19-7: EXTERNAL BLOCK TABLE READ (EBTRn) DISALLOWED: PIC18F1320

#### FIGURE 19-8: EXTERNAL BLOCK TABLE READ (EBTRn) ALLOWED: PIC18F1320

### 19.5.2 DATA EEPROM CODE PROTECTION

The entire data EEPROM is protected from external reads and writes by two bits: CPD and WRTD. CPD inhibits external reads and writes of data EEPROM. WRTD inhibits external writes to data EEPROM. The CPU can continue to read and write data EEPROM, regardless of the protection bit settings.

#### 19.5.3 CONFIGURATION REGISTER PROTECTION

The configuration registers can be write-protected. The WRTC bit controls protection of the configuration registers. In normal execution mode, the WRTC bit is readable only. WRTC can only be written via ICSP or an external programmer.

### 19.6 ID Locations

Eight memory locations (20000h-200007h) are designated as ID locations, where the user can store checksum or other code identification numbers. These locations are both readable and writable during normal execution through the TBLRD and TBLWT instructions, or during program/verify. The ID locations can be read when the device is code-protected.

### 19.7 In-Circuit Serial Programming

PIC18F1220/1320 microcontrollers can be serially programmed while in the end application circuit. This is simply done with two lines for clock and data and three other lines for power, ground and the programming voltage. This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed (see Table 19-4).

Note:	The Timer1 oscillator shares the T1OSI and T1OSO pins with the PGD and PGC pins used for programming and debugging.
	When using the Timer1 oscillator, In-Circuit Serial Programming (ICSP) may not function correctly (high voltage or low voltage), or the In-Circuit Debugger (ICD) may not communicate with the controller. As a result of using either ICSP or ICD, the Timer1 crystal may be damaged.
	If ICSP or ICD operations are required, the crystal should be disconnected from the circuit (disconnect either lead), or installed after programming. The oscillator loading capacitors may remain in-circuit during ICSP or ICD operation.

#### TABLE 19-4: ICSP/ICD CONNECTIONS

Signal	Pin	Notes
PGD	RB7/PGD/T1OSI/ P1D/KBI3	Shared with T1OSC – protect crystal
PGC	RB6/PGC/T1OSO/ T13CKI/P1C/KBI2	Shared with T1OSC – protect crystal
MCLR	MCLR/Vpp/RA5	
Vdd	Vdd	
Vss	Vss	
PGM	RB5/PGM/KBI1	Optional – pull RB5 low is LVP enabled

### 19.8 In-Circuit Debugger

When the DEBUG bit in configuration register, CONFIG4L, is programmed to a '0', the In-Circuit Debugger functionality is enabled. This function allows simple debugging functions when used with MPLAB<sup>®</sup> IDE. When the microcontroller has this feature enabled, some resources are not available for general use. Table 19-5 shows which resources are required by the background debugger.

#### TABLE 19-5: DEBUGGER RESOURCES

I/O pins:	RB6, RB7
Stack:	2 levels
Program Memory:	512 bytes
Data Memory:	10 bytes

To use the In-Circuit Debugger function of the microcontroller, the design must implement In-Circuit Serial Programming connections to MCLR/VPP, VDD, Vss, RB7 and RB6. This will interface to the In-Circuit Debugger module available from Microchip, or one of the third party development tool companies (see the note following **Section 19.7 "In-Circuit Serial Programming"** for more information).

### 19.9 Low-Voltage ICSP Programming

The LVP bit in configuration register, CONFIG4L, enables Low-Voltage Programming (LVP). When LVP is enabled, the microcontroller can be programmed without requiring high voltage being applied to the MCLR/VPP/RA5 pin, but the RB5/PGM/KB11 pin is then dedicated to controlling Program mode entry and is not available as a general purpose I/O pin.

LVP is enabled in erased devices.

While programming using LVP, VDD is applied to the MCLR/VPP/RA5 pin as in normal execution mode. To enter Programming mode, VDD is applied to the PGM pin.

- Note 1: High-voltage programming is always available, regardless of the state of the LVP bit or the PGM pin, by applying VIHH to the MCLR pin.
  - 2: When Low-Voltage Programming is enabled, the RB5 pin can no longer be used as a general purpose I/O pin.
  - **3:** When LVP is enabled, externally pull the PGM pin to Vss to allow normal program execution.

If Low-Voltage Programming mode will not be used, the LVP bit can be cleared and RB5/PGM/KBI1 becomes available as the digital I/O pin RB5. The LVP bit may be set or cleared only when using standard high-voltage programming (VIHH applied to the MCLR/VPP/RA5 pin). Once LVP has been disabled, only the standard high-voltage programming is available and must be used to program the device.

Memory that is not code-protected can be erased, using either a Block Erase, or erased row by row, then written at any specified VDD. If code-protected memory is to be erased, a Block Erase is required. If a Block Erase is to be performed when using Low-Voltage Programming, the device must be supplied with VDD of 4.5V to 5.5V.

NOTES:

### 20.0 INSTRUCTION SET SUMMARY

The PIC18 instruction set adds many enhancements to the previous PICmicro instruction sets, while maintaining an easy migration from these PICmicro instruction sets.

Most instructions are a single program memory word (16 bits), but there are three instructions that require two program memory locations.

Each single-word instruction is a 16-bit word divided into an opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction.

The instruction set is highly orthogonal and is grouped into four basic categories:

- Byte-oriented operations
- Bit-oriented operations
- Literal operations
- Control operations

The PIC18 instruction set summary in Table 20-1 lists **byte-oriented**, **bit-oriented**, **literal** and **control** operations. Table 20-1 shows the opcode field descriptions.

Most byte-oriented instructions have three operands:

- 1. The file register (specified by 'f')
- 2. The destination of the result (specified by 'd')
- 3. The accessed memory (specified by 'a')

The file register designator 'f' specifies which file register is to be used by the instruction.

The destination designator 'd' specifies where the result of the operation is to be placed. If 'd' is zero, the result is placed in the WREG register. If 'd' is one, the result is placed in the file register specified in the instruction.

All bit-oriented instructions have three operands:

- 1. The file register (specified by 'f')
- 2. The bit in the file register (specified by 'b')
- The accessed memory (specified by 'a')

The bit field designator 'b' selects the number of the bit affected by the operation, while the file register designator 'f' represents the number of the file in which the bit is located.

The **literal** instructions may use some of the following operands:

- A literal value to be loaded into a file register (specified by 'k')
- The desired FSR register to load the literal value into (specified by 'f')
- No operand required (specified by '—')

The **control** instructions may use some of the following operands:

- A program memory address (specified by 'n')
- The mode of the CALL or RETURN instructions (specified by 's')
- The mode of the table read and table write instructions (specified by 'm')
- No operand required (specified by '—')

All instructions are a single word, except for three double-word instructions. These three instructions were made double-word instructions so that all the required information is available in these 32 bits. In the second word, the 4 MSbs are '1's. If this second word is executed as an instruction (by itself), it will execute as a NOP.

All single-word instructions are executed in a single instruction cycle, unless a conditional test is true, or the program counter is changed as a result of the instruction. In these cases, the execution takes two instruction cycles, with the additional instruction cycle(s) executed as a NOP.

The double-word instructions execute in two instruction cycles.

One instruction cycle consists of four oscillator periods. Thus, for an oscillator frequency of 4 MHz, the normal instruction execution time is 1  $\mu$ s. If a conditional test is true, or the program counter is changed as a result of an instruction, the instruction execution time is 2  $\mu$ s. Two-word branch instructions (if true) would take 3  $\mu$ s.

Figure 20-1 shows the general formats that the instructions can have.

All examples use the format 'nnh' to represent a hexadecimal number, where 'h' signifies a hexadecimal digit.

The Instruction Set Summary, shown in Table 20-1, lists the instructions recognized by the Microchip Assembler (MPASM™). **Section 20.2** "Instruction **Set**" provides a description of each instruction.

### 20.1 Read-Modify-Write Operations

Any instruction that specifies a file register as part of the instruction performs a Read-Modify-Write (R-M-W) operation. The register is read, the data is modified and the result is stored according to either the instruction or the destination designator 'd'. A read operation is performed on a register even if the instruction writes to that register.

For example, a "BCF PORTB, 1" instruction will read PORTB, clear bit 1 of the data, then write the result back to PORTB. The read operation would have the unintended result that any condition that sets the RBIF flag would be cleared. The R-M-W operation may also copy the level of an input pin to its corresponding output latch.

### TABLE 20-1: OPCODE FIELD DESCRIPTIONS

Field	Description
a	RAM access bit
	a = 0: RAM location in Access RAM (BSR register is ignored)
	a = 1: RAM bank is specified by BSR register
bbb	Bit address within an 8-bit file register (0 to 7).
BSR	Bank Select Register. Used to select the current RAM bank.
d	Destination select bit
	d = 0: store result in WREG d = 1: store result in file register f
dest	Destination either the WREG register or the specified register file location.
f	8-bit register file address (0x00 to 0xFF).
fs	12-bit register file address (0x000 to 0xFFF). This is the source address.
fd	12-bit register file address (0x000 to 0xFFF). This is the destination address.
k	Literal field, constant data or label (may be either an 8-bit, 12-bit or a 20-bit value).
label	Label name.
	The mode of the TBLPTR register for the table read and table write instructions.
mm	Only used with table read and table write instructions:
*	No change to register (such as TBLPTR with table reads and writes)
*+	Post-Increment register (such as TBLPTR with table reads and writes)
*_	Post-Decrement register (such as TBLPTR with table reads and writes)
+*	Pre-Increment register (such as TBLPTR with table reads and writes)
n	The relative address (2's complement number) for relative branch instructions, or the direct address for
11	call/branch and return instructions.
PRODH	Product of Multiply High Byte.
PRODL	Product of Multiply Low Byte.
S	Fast Call/Return mode select bit
	s = 0: do not update into/from shadow registers
	s = 1: certain registers loaded into/from shadow registers (Fast mode)
u	Unused or unchanged.
WREG	Working register (accumulator).
x	Don't care ('0' or '1').
	The assembler will generate code with $x = 0$ . It is the recommended form of use for compatibility with all
	Microchip software tools.
TBLPTR	21-bit Table Pointer (points to a program memory location).
TABLAT	8-bit Table Latch.
TOS	Top-of-Stack.
PC	Program Counter.
PCL	Program Counter Low Byte.
PCH	Program Counter High Byte.
PCLATH	Program Counter High Byte Latch.
PCLATU	Program Counter Upper Byte Latch.
GIE	Global Interrupt Enable bit.
WDT	Watchdog Timer.
TO	Time-out bit.
PD	Power-down bit.
C, DC, Z, OV, N	ALU Status bits: Carry, Digit Carry, Zero, Overflow, Negative.
	Optional.
( )	Contents.
$\rightarrow$	Assigned to.
< >	Register bit field.
E	In the set of.
italics	User defined term (font is Courier).

## FIGURE 20-1: GENERAL FORMAT FOR INSTRUCTIONS

FIGURE 20-1:	GENERAL FORMAT FOR INSTRUCTIONS

BTG	fda	Bit Toggle f	1	0111	bbba	ffff	ffff	None	1, 2

**Note 1:** When a Port register is modified as a function of itself (e.g., MOVF PORTB, 1, 0), the value used will be that value present on the pins themselves. For example, if the data latch is '1' for a pin configured as input and is driven low by an external device, the data will be written back with a '0'.

2: If this instruction is executed on the TMR0 register (and where applicable, d = 1), the prescaler will be cleared if assigned.

3: If Program Counter (PC) is modified or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a NOP.

**4:** Some instructions are 2-word instructions. The second word of these instructions will be executed as a NOP, unless the first word of the instruction retrieves the information embedded in these 16 bits. This ensures that all program memory locations have a valid instruction.

5: If the table write starts the write cycle to internal memory, the write will continue until terminated.

2: If this instruction is executed on the TMR0 register (and where applicable, d = 1), the prescaler will be cleared if assigned.

**3:** If Program Counter (PC) is modified or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a NOP.

**4:** Some instructions are 2-word instructions. The second word of these instructions will be executed as a NOP, unless the first word of the instruction retrieves the information embedded in these 16 bits. This ensures that all program memory locations have a valid instruction.

5: If the table write starts the write cycle to internal memory, the write will continue until terminated.

### 20.2 Instruction Set

ADDLW	ADD litera	ADD literal to W					
Syntax:	[label] A	DDLW k					
Operands:	$0 \le k \le 25$	5					
Operation:	(W) + k $\rightarrow$	W					
Status Affected:	N, OV, C,	DC, Z					
Encoding:	0000	1111 kk	kk kkkk				
Description:		'k' and the	added to the result is				
Words:	1						
Cycles:	1						
Q Cycle Activity:							
Q1	Q2	Q3	Q4				
Decode	Read literal 'k'	Process Data	Write to W				
After Instruction	tion 0x10	x15					

ADDWF	ADD W to	o f					
Syntax:	[ label ] A	DDWF	f [,d	[,a]	]		
Operands:	0 ≤ f ≤ 255 d ∈ [0,1] a ∈ [0,1]						
Operation:	(W) + (f) -	$\rightarrow$ dest					
Status Affected:	N, OV, C,	DC, Z					
Encoding:	0010	01da	fff	f	ffff		
Description:	result is si result is si (default). Bank will	Add W to register 'f'. If 'd' is '0', the result is stored in W. If 'd' is '1', the result is stored back in register 'f' (default). If 'a' is '0', the Access Bank will be selected. If 'a' is '1', the BSR is used.					
Words:	1						
Cycles:	1						
Q Cycle Activity:							
Q1	Q2	Q3	3		Q4		
Decode	Read register 'f'	Proce Dat			rite to tination		
Example:	ADDWF	REG,	W				
Before Instru	iction						
W REG	= 0x17 = 0xC2						
After Instruct	ion						
W	= 0xD9						

REG

= 0xC2

ADD	OWFC	ADD W ar	nd Carry b	it to f		
Synt	ax:	[ <i>label</i> ] A[	DWFC	f [,d [,a	a]]	
Ope	rands:	0 ≤ f ≤ 255 d ∈ [0,1] a ∈ [0,1]	5			
Ope	ration:		(C) $\rightarrow$ des	st		
Statu	us Affected:	N, OV, C,	DC, Z			
Enco	oding:	0010	00da	ffff	ffff	
Des	Description: Add W, the Carry flag and data memory location 'f'. If 'd' is '0', the result is placed in W. If 'd' is '1', the result is placed in data memory location 'f'. If 'a' is '0', the Access Bank will be selected. If 'a' is '1', the BSR will not be overridden.

### 21.0 DEVELOPMENT SUPPORT

The PICmicro<sup>®</sup> microcontrollers are supported with a full range of hardware and software development tools:

- Integrated Development Environment
  - MPLAB® IDE Software
- Assemblers/Compilers/Linkers
  - MPASM<sup>™</sup> Assembler
  - MPLAB C17 and MPLAB C18 C Compilers
  - MPLINK<sup>™</sup> Object Linker/ MPLIB<sup>™</sup> Object Librarian
  - MPLAB C30 C Compiler
  - MPLAB ASM30 Assembler/Linker/Library
- Simulators
  - MPLAB SIM Software Simulator
  - MPLAB dsPIC30 Software Simulator
- Emulators
  - MPLAB ICE 2000 In-Circuit Emulator
  - MPLAB ICE 4000 In-Circuit Emulator
- In-Circuit Debugger
- MPLAB ICD 2
- Device Programmers
  - PRO MATE® II Universal Device Programmer
  - PICSTART® Plus Development Programmer
  - MPLAB PM3 Device Programmer
- Low-Cost Demonstration Boards
  - PICDEM<sup>™</sup> 1 Demonstration Board
  - PICDEM.net<sup>™</sup> Demonstration Board
  - PICDEM 2 Plus Demonstration Board
  - PICDEM 3 Demonstration Board
  - PICDEM 4 Demonstration Board
  - PICDEM 17 Demonstration Board
  - PICDEM 18R Demonstration Board
  - PICDEM LIN Demonstration Board
  - PICDEM USB Demonstration Board
- Evaluation Kits
  - KEELOQ<sup>®</sup> Evaluation and Programming Tools
  - PICDEM MSC
  - microID<sup>®</sup> Developer Kits
  - CAN
  - PowerSmart® Developer Kits
  - Analog

### 21.1 MPLAB Integrated Development Environment Software

The MPLAB IDE software brings an ease of software development previously unseen in the 8/16-bit microcontroller market. The MPLAB IDE is a Windows<sup>®</sup> based application that contains:

- An interface to debugging tools
  - simulator
  - programmer (sold separately)
  - emulator (sold separately)
  - in-circuit debugger (sold separately)
- · A full-featured editor with color coded context
- A multiple project manager
- Customizable data windows with direct edit of contents
- High-level source code debugging
- Mouse over variable inspection
- Extensive on-line help

The MPLAB IDE allows you to:

- Edit your source files (either assembly or C)
- One touch assemble (or compile) and download to PICmicro emulator and simulator tools (automatically updates all project information)
- Debug using:
  - source files (assembly or C)
  - mixed assembly and C
  - machine code

MPLAB IDE supports multiple debugging tools in a single development paradigm, from the cost effective simulators, through low-cost in-circuit debuggers, to full-featured emulators. This eliminates the learning curve when upgrading to tools with increasing flexibility and power.

#### 21.2 MPASM Assembler

The MPASM assembler is a full-featured, universal macro assembler for all PICmicro MCUs.

The MPASM assembler generates relocatable object files for the MPLINK object linker, Intel<sup>®</sup> standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code and COFF files for debugging.

The MPASM assembler features include:

- Integration into MPLAB IDE projects
- · User defined macros to streamline assembly code
- Conditional assembly for multi-purpose source files
- Directives that allow complete control over the assembly process

#### 21.3 MPLAB C17 and MPLAB C18 C Compilers

The MPLAB C17 and MPLAB C18 Code Development Systems are complete ANSI C compilers for Microchip's PIC17CXXX and PIC18CXXX family of microcontrollers. These compilers provide powerful integration capabilities, superior code optimization and ease of use not found with other compilers.

For easy source level debugging, the compilers provide symbol information that is optimized to the MPLAB IDE debugger.

#### 21.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK object linker combines relocatable objects created by the MPASM assembler and the MPLAB C17 and MPLAB C18 C compilers. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB object librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

### 21.5 MPLAB C30 C Compiler

The MPLAB C30 C compiler is a full-featured, ANSI compliant, optimizing compiler that translates standard ANSI C programs into dsPIC30F assembly language source. The compiler also supports many command line options and language extensions to take full advantage of the dsPIC30F device hardware capabilities and afford fine control of the compiler code generator.

MPLAB C30 is distributed with a complete ANSI C standard library. All library functions have been validated and conform to the ANSI C library standard. The library includes functions for string manipulation, dynamic memory allocation, data conversion, timekeeping and math functions (trigonometric, exponential and hyperbolic). The compiler provides symbolic information for high-level source debugging with the MPLAB IDE.

## 21.6 MPLAB ASM30 Assembler, Linker and Librarian

MPLAB ASM30 assembler produces relocatable machine code from symbolic assembly language for dsPIC30F devices. MPLAB C30 compiler uses the assembler to produce it's object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire dsPIC30F instruction set
- Support for fixed-point and floating-point data
- Command line interface
- Rich directive set
- Flexible macro language
- MPLAB IDE compatibility

#### 21.7 MPLAB SIM Software Simulator

The MPLAB SIM software simulator allows code development in a PC hosted environment by simulating the PICmicro series microcontrollers on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a file, or user defined key press, to any pin. The execution can be performed in Single-Step, Execute Until Break or Trace mode.

The MPLAB SIM simulator fully supports symbolic debugging using the MPLAB C17 and MPLAB C18 C Compilers, as well as the MPASM assembler. The software simulator offers the flexibility to develop and debug code outside of the laboratory environment, making it an excellent, economical software development tool.

#### 21.8 MPLAB SIM30 Software Simulator

The MPLAB SIM30 software simulator allows code development in a PC hosted environment by simulating the dsPIC30F series microcontrollers on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a file, or user defined key press, to any of the pins.

The MPLAB SIM30 simulator fully supports symbolic debugging using the MPLAB C30 C Compiler and MPLAB ASM30 assembler. The simulator runs in either a Command Line mode for automated tasks, or from MPLAB IDE. This high-speed simulator is designed to debug, analyze and optimize time intensive DSP routines.

#### 21.9 MPLAB ICE 2000 High-Performance Universal In-Circuit Emulator

The MPLAB ICE 2000 universal in-circuit emulator is intended to provide the product development engineer with a complete microcontroller design tool set for PICmicro microcontrollers. Software control of the MPLAB ICE 2000 in-circuit emulator is advanced by the MPLAB Integrated Development Environment, which allows editing, building, downloading and source debugging from a single environment.

The MPLAB ICE 2000 is a full-featured emulator system with enhanced trace, trigger and data monitoring features. Interchangeable processor modules allow the system to be easily reconfigured for emulation of different processors. The universal architecture of the MPLAB ICE in-circuit emulator allows expansion to support new PICmicro microcontrollers.

The MPLAB ICE 2000 in-circuit emulator system has been designed as a real-time emulation system with advanced features that are typically found on more expensive development tools. The PC platform and Microsoft<sup>®</sup> Windows 32-bit operating system were chosen to best make these features available in a simple, unified application.

### 21.10 MPLAB ICE 4000 High-Performance Universal In-Circuit Emulator

The MPLAB ICE 4000 universal in-circuit emulator is intended to provide the product development engineer with a complete microcontroller design tool set for highend PICmicro microcontrollers. Software control of the MPLAB ICE in-circuit emulator is provided by the MPLAB Integrated Development Environment, which allows editing, building, downloading and source debugging from a single environment.

The MPLAB ICD 4000 is a premium emulator system, providing the features of MPLAB ICE 2000, but with increased emulation memory and high-speed performance for dsPIC30F and PIC18XXXX devices. Its advanced emulator features include complex triggering and timing, up to 2 Mb of emulation memory and the ability to view variables in real-time.

The MPLAB ICE 4000 in-circuit emulator system has been designed as a real-time emulation system with advanced features that are typically found on more expensive development tools. The PC platform and Microsoft Windows 32-bit operating system were chosen to best make these features available in a simple, unified application.

### 21.11 MPLAB ICD 2 In-Circuit Debugger

Microchip's In-Circuit Debugger, MPLAB ICD 2, is a powerful, low-cost, run-time development tool, connecting to the host PC via an RS-232 or high-speed USB interface. This tool is based on the Flash PICmicro MCUs and can be used to develop for these and other PICmicro microcontrollers. The MPLAB ICD 2 utilizes the in-circuit debugging capability built into the Flash devices. This feature, along with Microchip's In-Circuit Serial Programming<sup>™</sup> (ICSP<sup>™</sup>) protocol, offers cost effective in-circuit Flash debugging from the graphical user interface of the MPLAB Integrated Development Environment. This enables a designer to develop and debug source code by setting breakpoints, single-stepping and watching variables, CPU status and peripheral registers. Running at full speed enables testing hardware and applications in real-time. MPLAB ICD 2 also serves as a development programmer for selected PICmicro devices.

#### 21.12 PRO MATE II Universal Device Programmer

The PRO MATE II is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features an LCD display for instructions and error messages and a modular detachable socket assembly to support various package types. In Stand-Alone mode, the PRO MATE II device programmer can read, verify and program PICmicro devices without a PC connection. It can also set code protection in this mode.

### 21.13 MPLAB PM3 Device Programmer

The MPLAB PM3 is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages and a modular detachable socket assembly to support various package types. The ICSP<sup>™</sup> cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 device programmer can read, verify and program PICmicro devices without a PC connection. It can also set code protection in this mode. MPLAB PM3 connects to the host PC via an RS-232 or USB cable. MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices and incorporates an SD/MMC card for file storage and secure data applications.

#### 21.14 PICSTART Plus Development Programmer

The PICSTART Plus development programmer is an easy-to-use, low-cost, prototype programmer. It connects to the PC via a COM (RS-232) port. MPLAB Integrated Development Environment software makes using the programmer simple and efficient. The PICSTART Plus development programmer supports most PICmicro devices up to 40 pins. Larger pin count devices, such as the PIC16C92X and PIC17C76X, may be supported with an adapter socket. The PICSTART Plus development programmer is CE compliant.

#### 21.15 PICDEM 1 PICmicro Demonstration Board

The PICDEM 1 demonstration board demonstrates the capabilities of the PIC16C5X (PIC16C54 to PIC16C58A), PIC16C61, PIC16C62X, PIC16C71, PIC16C8X, PIC17C42, PIC17C43 and PIC17C44. All necessary hardware and software is included to run basic demo programs. The sample microcontrollers provided with the PICDEM 1 demonstration board can be programmed with a PRO MATE II device programmer or a PICSTART Plus development programmer. The PICDEM 1 demonstration board can be connected to the MPLAB ICE in-circuit emulator for testing. A prototype area extends the circuitry for additional application components. Features include an RS-232 interface, a potentiometer for simulated analog input, push button switches and eight LEDs.

#### 21.16 PICDEM.net Internet/Ethernet Demonstration Board

The PICDEM.net demonstration board is an Internet/ Ethernet demonstration board using the PIC18F452 microcontroller and TCP/IP firmware. The board supports any 40-pin DIP device that conforms to the standard pinout used by the PIC16F877 or PIC18C452. This kit features a user friendly TCP/IP stack, web server with HTML, a 24L256 Serial EEPROM for Xmodem download to web pages into Serial EEPROM, ICSP/MPLAB ICD 2 interface connector, an Ethernet interface, RS-232 interface and a 16 x 2 LCD display. Also included is the book and CD-ROM *"TCP/IP Lean, Web Servers for Embedded Systems,"* by Jeremy Bentham

### 21.17 PICDEM 2 Plus Demonstration Board

The PICDEM 2 Plus demonstration board supports many 18, 28 and 40-pin microcontrollers, including PIC16F87X and PIC18FXX2 devices. All the necessary hardware and software is included to run the demonstration programs. The sample microcontrollers provided with the PICDEM 2 demonstration board can be programmed with a PRO MATE II device programmer, PICSTART Plus development programmer, or MPLAB ICD 2 with a Universal Programmer Adapter. The MPLAB ICD 2 and MPLAB ICE in-circuit emulators may also be used with the PICDEM 2 demonstration board to test firmware. A prototype area extends the circuitry for additional application components. Some of the features include an RS-232 interface, a 2 x 16 LCD display, a piezo speaker, an on-board temperature sensor, four LEDs and sample PIC18F452 and PIC16F877 Flash microcontrollers.

### 21.18 PICDEM 3 PIC16C92X Demonstration Board

The PICDEM 3 demonstration board supports the PIC16C923 and PIC16C924 in the PLCC package. All the necessary hardware and software is included to run the demonstration programs.

### 21.19 PICDEM 4 8/14/18-Pin Demonstration Board

The PICDEM 4 can be used to demonstrate the capabilities of the 8, 14 and 18-pin PIC16XXXX and PIC18XXXX MCUs, including the PIC16F818/819, PIC16F87/88, PIC16F62XA and the PIC18F1320 family of microcontrollers. PICDEM 4 is intended to showcase the many features of these low pin count parts, including LIN and Motor Control using ECCP. Special provisions are made for low-power operation with the supercapacitor circuit and jumpers allow onboard hardware to be disabled to eliminate current draw in this mode. Included on the demo board are provisions for Crystal, RC or Canned Oscillator modes, a five volt regulator for use with a nine volt wall adapter or battery, DB-9 RS-232 interface, ICD connector for programming via ICSP and development with MPLAB ICD 2, 2 x 16 liquid crystal display, PCB footprints for H-Bridge motor driver, LIN transceiver and EEPROM. Also included are: header for expansion, eight LEDs, four potentiometers, three push buttons and a prototyping area. Included with the kit is a PIC16F627A and a PIC18F1320. Tutorial firmware is included along with the User's Guide.

### 21.20 PICDEM 17 Demonstration Board

The PICDEM 17 demonstration board is an evaluation board that demonstrates the capabilities of several Microchip microcontrollers, including PIC17C752, PIC17C756A, PIC17C762 and PIC17C766. A programmed sample is included. The PRO MATE II device programmer, or the PICSTART Plus development programmer, can be used to reprogram the device for user tailored application development. The PICDEM 17 demonstration board supports program download and execution from external on-board Flash memory. A generous prototype area is available for user hardware expansion.

#### 21.21 PICDEM 18R PIC18C601/801 Demonstration Board

The PICDEM 18R demonstration board serves to assist development of the PIC18C601/801 family of Microchip microcontrollers. It provides hardware implementation of both 8-bit Multiplexed/Demultiplexed and 16-bit Memory modes. The board includes 2 Mb external Flash memory and 128 Kb SRAM memory, as well as serial EEPROM, allowing access to the wide range of memory types supported by the PIC18C601/801.

### 21.22 PICDEM LIN PIC16C43X Demonstration Board

The powerful LIN hardware and software kit includes a series of boards and three PICmicro microcontrollers. The small footprint PIC16C432 and PIC16C433 are used as slaves in the LIN communication and feature on-board LIN transceivers. A PIC16F874 Flash microcontroller serves as the master. All three micro-controllers are programmed with firmware to provide LIN bus communication.

### 21.23 PICkit<sup>™</sup> 1 Flash Starter Kit

A complete "development system in a box", the PICkit<sup>™</sup> Flash Starter Kit includes a convenient multi-section board for programming, evaluation and development of 8/14-pin Flash PICr8r94h1.1978 TM9( a)]TJ.30.0.1.3(u).041(r)2a7.r6NM

NOTES:

### 22.0 ELECTRICAL CHARACTERISTICS

### Absolute Maximum Ratings<sup>(†)</sup>

Ambient temperature under bias	40°C to +125°C
Storage temperature	65°C to +150°C
Voltage on any pin with respect to Vss (except VDD, MCLR and RA4)	0.3V to (VDD + 0.3V)
Voltage on VDD with respect to Vss	0.3V to +5.5V
Voltage on MCLR with respect to Vss (Note 2)	0V to +13.25V
Voltage on RA4 with respect to Vss	0V to +8.5V
Total power dissipation (Note 1)	
Maximum current out of Vss pin	300 mA
Maximum current into VDD pin	250 mA
Input clamp current, Iικ (Vι < 0 or Vι > VDD)	±20 mA
Output clamp current, Iok (Vo < 0 or Vo > VDD)	±20 mA
Maximum output current sunk by any I/O pin	25 mA
Maximum output current sourced by any I/O pin	25 mA
Maximum current sunk by all ports	200 mA
Maximum current sourced by all ports	200 mA

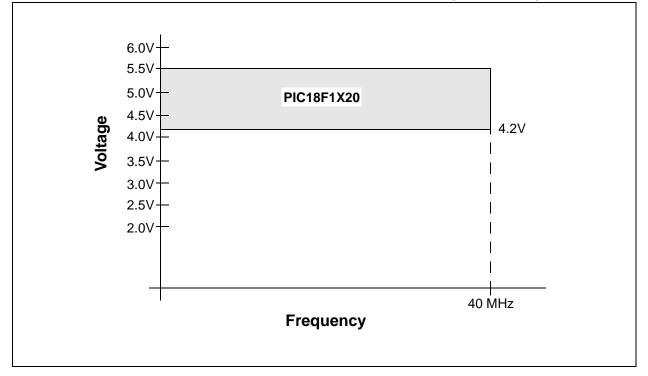

**Note 1:** Power dissipation is calculated as follows:

 $\mathsf{Pdis} = \mathsf{VDD} \ x \ \{\mathsf{IDD} - \sum \mathsf{IOH}\} + \sum \{(\mathsf{VDD} - \mathsf{VOH}) \ x \ \mathsf{IOH}\} + \sum (\mathsf{VOL} \ x \ \mathsf{IOL})$ 

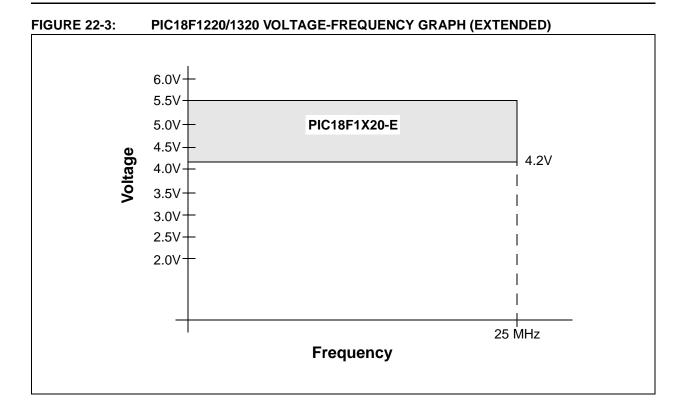

**2:** Voltage spikes below Vss at the MCLR/VPP pin, inducing currents greater than 80 mA, may cause latch-up. Thus, a series resistor of 50-100Ω should be used when applying a "low" level to the MCLR/VPP pin, rather than pulling this pin directly to Vss.

† NOTICE: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

#### 22.1 DC Characteristics: Supply Voltage PIC18F1220/1320 (Industrial) PIC18LF1220/1320 (Industrial)

Legend: Shading of rows is to assist in readability of the table.

Note 1: This is the limit to which VDD can be lowered in Sleep mode, or during a device Reset, without losing RAM data.

2: When BOR is on and BORV<1:0> = 0x, the device will operate correctly at 40 MHz for any VDD at which the BOR allows execution (low-voltage and industrial devices only).

3: When BOR is on and BORV<1:0> = 0x, the device will operate correctly at 25 MHz for any VDD at which the BOR allows execution (extended devices only).

**Note 1:** The power-down current in Sleep mode does not depend on the oscillator type. Power-down current is measured with the part in Sleep mode, with all I/O pins in high-impedance state and tied to VDD or VSS and all features that add delta current disabled (such as WDT, Timer1 Oscillator, BOR, etc.).

2: The supply current is mainly a function of operating voltage, frequency and mode. Other factors, such as I/O pin loading and switching rate, oscillator type and circuit, internal code execution pattern and temperature, also have an impact on the current consumption.

The test conditions for all IDD measurements in active operation mode are:

- OSC1 = external square wave, from rail-to-rail; all I/O pins tri-stated, pulled to VDD;
- MCLR = VDD; WDT enabled/disabled as specified.
- 3: For RC oscillator configurations, current through REXT is not included. The current through the resistor can be estimated by the formula Ir = VDD/2REXT (mA) with REXT in kΩ.
- 4: Standard low-cost 32 kHz crystals have an operating temperature range of -10°C to +70°C. Extended temperature crystals are available at a much higher cost.

MCLR = VDD; WDT enabled/disabled as specified.

- 3: For RC oscillator configurations, current through REXT is not included. The current through the resistor can be estimated by the formula Ir = VDD/2REXT (mA) with REXT in kΩ.
- 4: Standard low-cost 32 kHz crystals have an operating temperature range of -10°C to +70°C. Extended temperature crystals are available at a much higher cost.

		1.0	8.0	μA	-40°C to +125°C	VDD = 5.0V					

Legend: Shading of rows is to assist in readability of the table.

**Note 1:** The power-down current in Sleep mode does not depend on the oscillator type. Power-down current is measured with the part in Sleep mode, with all I/O pins in high-impedance state and tied to VDD or VSS and all features that add delta current disabled (such as WDT, Timer1 Oscillator, BOR, etc.).

2: The supply current is mainly a function of operating voltage, frequency and mode. Other factors, such as I/O pin loading and switching rate, oscillator type and circuit, internal code execution pattern and temperature, also have an impact on the current consumption.

The test conditions for all IDD measurements in active operation mode are:

OSC1 = external square wave, from rail-to-rail; all I/O pins tri-stated, pulled to VDD;

- MCLR = VDD; WDT enabled/disabled as specified.
- **3:** For RC oscillator configurations, current through REXT is not included. The current through the resistor can be estimated by the formula Ir = VDD/2REXT (mA) with REXT in kΩ.
- 4: Standard low-cost 32 kHz crystals have an operating temperature range of -10°C to +70°C. Extended temperature crystals are available at a much higher cost.

## 22.4 AC (Timing) Characteristics

#### 22.4.1 TIMING PARAMETER SYMBOLOGY

The timing parameter symbols have been created following one of the following formats:

1. TppS2ppS	8	3. TCC:ST	(I <sup>2</sup> C specifications only)
2. TppS		4. Ts	(I <sup>2</sup> C specifications only)
Т			
F	Frequency	Т	Time
Lowercase le	etters (pp) and their meanings:		
рр			
сс	CCP1	osc	OSC1
ck	CLKO	rd	RD
cs	CS	rw	RD or WR
di	SDI	SC	SCK
do	SDO	SS	SS
dt	Data in	tO	TOCKI
io	I/O port	t1	T13CKI
mc	MCLR	wr	WR
Uppercase le	etters and their meanings:		
S			
F	Fall	Р	Period
н	High	R	Rise
I	Invalid (High-Impedance)	V	Valid
L	Low	Z	High-Impedance
I <sup>2</sup> C only			
AA	output access	High	High
BUF	Bus free	Low	Low
TCC:ST (I <sup>2</sup> C s	specifications only)		
CC			
HD	Hold	SU	Setup
ST			
DAT	DATA input hold	STO	Stop condition
STA	Start condition		

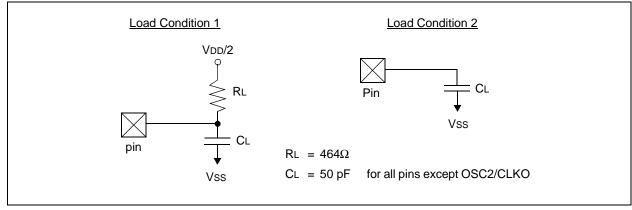

## 22.4.2 TIMING CONDITIONS

The temperature and voltages specified in Table 22-3 apply to all timing specifications unless otherwise noted. Figure 22-5 specifies the load conditions for the timing specifications.

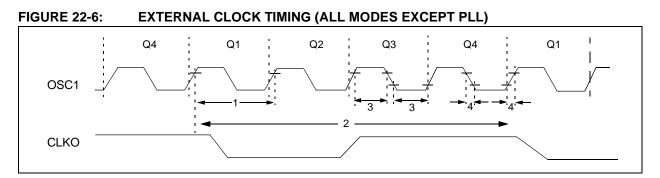

## TABLE 22-3: TEMPERATURE AND VOLTAGE SPECIFICATIONS – AC

	Standard Operating Conditions (unless otherwise stated)							
	Operating temperature $-40^{\circ}C \le TA \le +85^{\circ}C$ for industrial							
AC CHARACTERISTICS	$-40^{\circ}C \le TA \le +125^{\circ}C$ for extended							
AC CHARACTERISTICS	Operating voltage VDD range as described in DC spec Section 22.1 and							
	Section 22.3							
	LF parts operate for industrial temperatures only.							

## FIGURE 22-5: LOAD CONDITIONS FOR DEVICE TIMING SPECIFICATIONS

### 22.4.3 TIMING DIAGRAMS AND SPECIFICATIONS

#### TABLE 22-4: EXTERNAL CLOCK TIMING REQUIREMENTS

Param. No.	Symbol	Characteristic	Min	Max	Units	Conditions
1A	Fosc	External CLKI Frequency <sup>(1)</sup>	DC	40	MHz	EC, ECIO (LF and Industrial)
			DC	25	MHz	EC, ECIO (Extended)
		Oscillator Frequency <sup>(1)</sup>	DC	4	MHz	RC oscillator
			DC	1	MHz	XT oscillator
			DC	25	MHz	HS oscillator
			1	10	MHz	HS + PLL oscillator
			DC	33	kHz	LP Oscillator mode
1	Tosc	External CLKI Period <sup>(1)</sup>	25	—	ns	EC, ECIO (LF and Industrial)
			40	—	ns	EC, ECIO (Extended)
		Oscillator Period <sup>(1)</sup>	250	—	ns	RC oscillator
			1000	—	ns	XT oscillator
			25	—	ns	HS oscillator
			100	1000	ns	HS + PLL oscillator
		(1)	30		μs	LP oscillator
2	Тсү	Instruction Cycle Time <sup>(1)</sup>	100	_	ns	TCY = 4/FOSC
3	TosL,	External Clock in (OSC1)	30	—	ns	XT oscillator
	TosH	High or Low Time	2.5	—	μs	LP oscillator
			10	—	ns	HS oscillator
4	TosR,	External Clock in (OSC1)	—	20	ns	XT oscillator
	TosF	Rise or Fall Time	—	50	ns	LP oscillator
			—	7.5	ns	HS oscillator

Note 1: Instruction cycle period (Tcr) equals four times the input oscillator time base period for all configurations except PLL. All specified values are based on characterization data for that particular oscillator type under standard operating conditions, with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at "min." values with an external clock applied to the OSC1/CLKI pin. When an external clock input is used, the "max." cycle time limit is "DC" (no clock) for all devices.

Param No.	Sym	Characteristic	Min	Тур†	Max	Units	Conditions		
F10	Fosc	Oscillator Frequency Range	4		10	MHz	HS and HSPLL mode only		
F11	Fsys	On-Chip VCO System Frequency	16	_	40	MHz	HSPLL mode only		
F12	Tpll	PLL Start-up Time (Lock Time)	_	_	2	ms	HSPLL mode only		
F13	$\Delta CLK$	CLKO Stability (Jitter)	-2		+2	%	HSPLL mode only		

#### TABLE 22-5:PLL CLOCK TIMING SPECIFICATIONS, HS/HSPLL MODE (VDD = 4.2V TO 5.5V)

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

## TABLE 22-6:INTERNAL RC ACCURACY: PIC18F1220/1320 (INDUSTRIAL)PIC18LF1220/1320 (INDUSTRIAL)

PIC18LF1 (Indus	<b>1220/1320</b> strial)	Standard Operating Conditions (unless otherwise stated)Operating temperature $-40^{\circ}C \le TA \le +85^{\circ}C$ for industrial

#### TABLE 22-13: A/D CONVERTER CHARACTERISTICS: PIC18F1220/1320 (INDUSTRIAL) PIC18LF1220/1320 (INDUSTRIAL)

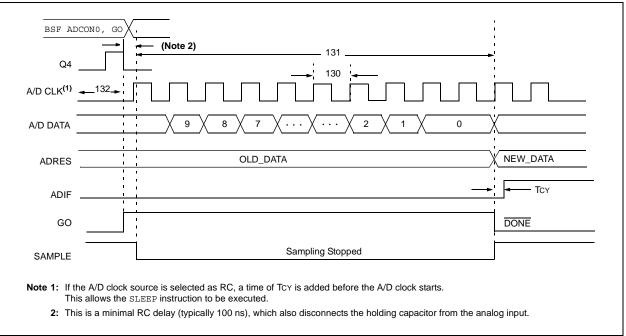

Param No.	Symbol	Charact	eristic	Min	Тур	Мах	Units	Conditions
A01	NR	Resolution		—	_	10	bit	$\Delta VREF \ge 3.0V$
A03	EIL	Integral Linearity	Error	—	_	<±1	LSb	$\Delta VREF \ge 3.0V$
A04	Edl	Differential Linea	rity Error	—	_	<±1	LSb	$\Delta VREF \ge 3.0V$
A06	EOFF	Offset Error		—	_	<±1	LSb	$\Delta VREF \ge 3.0V$
A07	Egn	Gain Error		—	_	<±1	LSb	$\Delta VREF \ge 3.0V$
A10	_	Monotonicity		gu	arantee	j(2)	—	
A20	$\Delta VREF$	Reference Voltage Range (VREFH – VREFL)		3	—	AVDD – AVSS	V	For 10-bit resolution
A21	Vrefh	Reference Voltage High		AVss + 3.0V	_	AVDD + 0.3V	V	For 10-bit resolution
A22	Vrefl	Reference Voltage Low		AVss-0.3V	—	AVDD - 3.0V	V	For 10-bit resolution
A25	VAIN	Analog Input Voltage		VREFL	—	Vrefh	V	
A28	AVdd	Analog Supply V	oltage	Vdd - 0.3	_	Vdd + 0.3	V	
A29	AVss	Analog Supply V	oltage	Vss – 0.3	_	Vss + 0.3	V	
A30	ZAIN	Recommended Impedance of Analog Voltage Source		—	—	2.5	kΩ	
A40	IAD	A/D Conversion PIC18F1X20		—	180	—	μA	Average current
		Current (VDD)	PIC18LF1X20	—	90	—	μA	consumption when A/D is on <b>(Note 1)</b>
A50	IREF	VREF Input Current (Note 3)		—	_	±5 ±150	μΑ μΑ	During VAIN acquisition. During A/D conversion cycle.

**Note 1:** When A/D is off, it will not consume any current other than minor leakage current. The power-down current specification includes any such leakage from the A/D module.

2: The A/D conversion result never decreases with an increase in the input voltage and has no missing codes.

**3:** VREFH current is from RA3/AN3/VREF+ pin or AVDD, whichever is selected as the VREFH source. VREFL current is from RA2/AN2/VREF- pin or AVss, whichever is selected as the VREFL source.

## TABLE 22-14: A/D CONVERSION REQUIREMENTS

Param No.	Symbol	Characteristic		Min	Мах	Units	Conditions
130	TAD	A/D Clock Period	d PIC18F1X20		20 <sup>(5)</sup>	μs	Tosc based, VREF ≥ 3.0V
			PIC18LF1X20	3.0	20 <sup>(5)</sup>	μs	Tosc based, VREF full range
			PIC18F1X20	2.0	6.0	μs	A/D RC mode
			PIC18LF1X20	3.0	9.0	μs	A/D RC mode
131	TCNV	Conversion Time (not including acquisition	11	12	Tad		
132	TACQ	Acquisition Time (Note 3)		15 10	_	μs μs	$-40^{\circ}C \le Temp \le +125^{\circ}C$ $0^{\circ}C \le Temp \le +125^{\circ}C$
135	Tswc	Switching Time from C	_	(Note 4)			
136	Тамр	Amplifier Settling Time	1	_	μs	This may be used if the "new" input voltage has not changed by more than 1 LSb (i.e., 5 mV @ 5.12V) from the last sampled voltage (as stated on CHOLD).	

Note 1: ADRES register may be read on the following TCY cycle.

2: See Section 17.0 "10-Bit Analog-to-Digital Converter (A/D) Module" for minimum conditions when input voltage has changed more than 1 LSb.

**3:** The time for the holding capacitor to acquire the "New" input voltage, when the voltage changes full scale after the conversion (AVDD to AVss, or AVss to AVDD). The source impedance (Rs) on the input channels is 50 $\Omega$ .

- 4: On the next Q4 cycle of the device clock.
- 5: The time of the A/D clock period is dependent on the device frequency and the TAD clock divider.

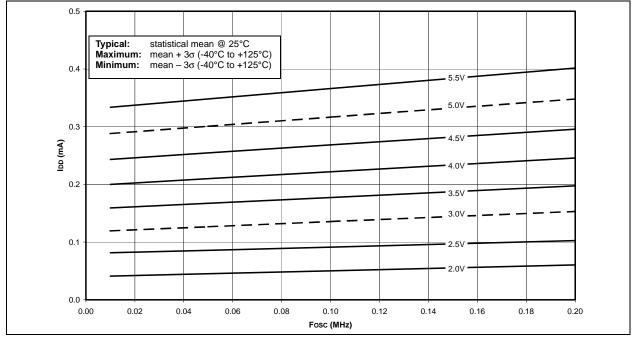

NOTES:

## 23.0 DC AND AC CHARACTERISTICS GRAPHS AND TABLES

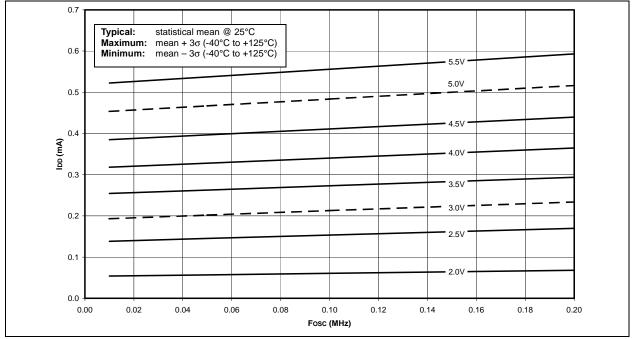

**Note:** The graphs and tables provided following this note are a statistical summary based on a limited number of samples and are provided for informational purposes only. The performance characteristics listed herein are not tested or guaranteed. In some graphs or tables, the data presented may be outside the specified operating range (e.g., outside specified power supply range) and therefore, outside the warranted range.

"Typical" represents the mean of the distribution at 25°C. "Maximum" or "minimum" represents (mean +  $3\sigma$ ) or (mean -  $3\sigma$ ) respectively, where  $\sigma$  is a standard deviation, over the whole temperature range.

# PIC18F1220/1320

NOTES:

# APPENDIX A: REVISION HISTORY

## **Revision A (August 2002)**

Original data sheet for PIC18F1220/1320 devices.

## **Revision B (November 2002)**

This revision includes significant changes to **Section 2.0**, **Section 3.0** and **Section 19.0**, as well as updates to the Electrical Specifications in **Section 22.0** and includes minor corrections to the data sheet text.

## Revision C (May 2004)

This revision includes updates to the Electrical Specifications in **Section 22.0**, the DC and AC Characteristics Graphs and Tables in **Section 23.0** and includes minor corrections to the data sheet text.

Features	PIC18F1220	PIC18F1320
Program Memory (Bytes)	4096	8192
Program Memory (Instructions)	2048	4096
Interrupt Sources	15	15
I/O Ports	Ports A, B	Ports A, B
Enhanced Capture/Compare/PWM Modules	1	1
10-bit Analog-to-Digital Module	7 input channels	7 input channels
Packages	18-pin SDIP 18-pin SOIC 20-pin SSOP 28-pin QFN	18-pin SDIP 18-pin SOIC 20-pin SSOP 28-pin QFN

## TABLE B-1: DEVICE DIFFERENCES

# APPENDIX B: DEVICE DIFFERENCES

The differences between the devices listed in this data sheet are shown in Table B-1.

# APPENDIX C: CONVERSION CONSIDERATIONS

This appendix discusses the considerations for converting from previous versions of a device to the ones listed in this data sheet. Typically, these changes are due to the differences in the process technology used. An example of this type of conversion is from a PIC16C74A to a PIC16C74B.

Not Applicable

# APPENDIX D: MIGRATION FROM BASELINE TO ENHANCED DEVICES

This section discusses how to migrate from a baseline device (i.e., PIC16C5X) to an enhanced MCU device (i.e., PIC18FXXX).

The following are the list of modifications over the PIC16C5X microcontroller family:

Not Currently Available

# APPENDIX E: MIGRATION FROM MID-RANGE TO ENHANCED DEVICES

A detailed discussion of the differences between the mid-range MCU devices (i.e., PIC16CXXX) and the enhanced devices (i.e., PIC18FXXX) is provided in *AN716, "Migrating Designs from PIC16C74A/74B to PIC18C442".* The changes discussed, while device specific, are generally applicable to all mid-range to enhanced device migrations.

This Application Note is available as Literature Number DS00716.

# APPENDIX F: MIGRATION FROM HIGH-END TO ENHANCED DEVICES

A detailed discussion of the migration pathway and differences between the high-end MCU devices (i.e., PIC17CXXX) and the enhanced devices (i.e., PIC18FXXX) is provided in *AN726, "PIC17CXXX to PIC18CXXX Migration"*.

This Application Note is available as Literature Number DS00726.

NOTES:

# **ON-LINE SUPPORT**

Microchip provides on-line support on the Microchip World Wide Web site.

The web site is used by Microchip as a means to make files and information easily available to customers. To view the site, the user must have access to the Internet and a web browser, such as Netscape<sup>®</sup> or Microsoft<sup>®</sup> Internet Explorer. Files are also available for FTP download from our FTP site.

# Connecting to the Microchip Internet Web Site

The Microchip web site is available at the following URL:

#### www.microchip.com

The file transfer site is available by using an FTP service to connect to:

#### ftp://ftp.microchip.com

The web site and file transfer site provide a variety of services. Users may download files for the latest Development Tools, Data Sheets, Application Notes, User's Guides, Articles and Sample Programs. A variety of Microchip specific business information is also available, including listings of Microchip sales offices, distributors and factory representatives. Other data available for consideration is:

- Latest Microchip Press Releases
- Technical Support Section with Frequently Asked Questions
- Design Tips
- Device Errata
- Job Postings
- Microchip Consultant Program Member Listing
- Links to other useful web sites related to Microchip Products
- Conferences for products, Development Systems, technical information and more
- · Listing of seminars and events

# SYSTEMS INFORMATION AND UPGRADE HOT LINE

The Systems Information and Upgrade Line provides system users a listing of the latest versions of all of Microchip's development systems software products. Plus, this line provides information on how customers can receive the most current upgrade kits. The Hot Line Numbers are:

1-800-755-2345 for U.S. and most of Canada and

1-480-792-7302 for the rest of the world.

# **READER RESPONSE**

It is our intention to provide you with the best documentation possible to ensure successful use of your Microchip product. If you wish to provide your comments on organization, clarity, subject matter and ways in which our documentation can better serve you, please FAX your comments to the Technical Publications Manager at (480) 792-4150.

Please list the following information and use this outline to provide us with your comments about this document.

# PIC18F1220/1320 PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

PART NO. Device	− X /XX XXX       Temperature Package Pattern Range	Examples: a) PIC18LF1320-I/P 301 = Industrial temp., PDIP package, Extended VDD limits, QTP pattern #301.
Device	PIC18F1220/1320 <sup>(1)</sup> , PIC18F1220/1320T <sup>(2)</sup> ; VDD range 4.2V to 5.5V PIC18LF1220/1320 <sup>(1)</sup> , PIC18LF1220/1320T <sup>(2)</sup> ; VDD range 2.5V to 5.5V	b) PIC18LF1220-I/SO = Industrial temp., SOIC package, Extended VDD limits.
Temperature Range	I = $-40^{\circ}$ C to $+85^{\circ}$ C (Industrial) E = $-40^{\circ}$ C to $+125^{\circ}$ C (Extended)	Note 1: F = Standard Voltage range LF = Wide Voltage Range 2: T = in tape and reel – SOIC
Package	SO = SOICSS = SSOPP = PDIPML = QFN	package only
Pattern	QTP, SQTP, Code or Special Requirements (blank otherwise)
